WATT, James, a philosopher, mechanician, and civil engineer, whose inventive talents, extensive knowledge of the sciences and arts, and practical application of them to the purposes of life, place him in the foremost rank of those illustrious men whose discoveries have influenced the state of society, and conferred distinction upon their country and age. His great-grandfather farmed his own small estate in the county of Aberdeen, but engaging in the civil wars, was killed in one of Montrose's battles, and his property lost to his family. His son, Thomas Watt, left an infant, was brought up by relations, and having a turn for the mathematical sciences, made such proficiency by his own exertions, under very untoward circumstances, occasioned by the persecutions of the times, as to enable him at a later and quieter period to establish himself at Greenock as a teacher of these sciences, and of the dependent arts of surveying and navigation. There he acquired reputation, and dying in 1734, at the advanced age of ninety-one, left a brief record of his partiality to his profession in the inscription upon his tomb in the West Church-yard. He is there styled professor of the mathematics. He had two sons, John and James; the former, brought up as a mathematician, settled first at Ayr, and afterwards at Glasgow, where he was much employed in surveying and directing the improvement of estates; was an able man, and drew neatly and accurately, which was not very common in those days. He died in 1737, at an early age, leaving "A Survey of the River Clyde, from Glasgow to the Point of Toward," which was published by his brother several years afterwards. James, his younger brother, of an active, ingenious, and enterprising mind, became a merchant in Greenock, and was for upwards of twenty years a member of the town council, a magistrate, and a zealous promoter of the improvements of the town. By his wife, Agnes Muirhead, he had two sons, James, the subject of the present article, and John, a youth of promising abilities, who was lost at sea soon after he became of age. Misfortunes in trade, and the decay of the faculties of his mind, occasioned his retirement from business some years before his death, which happened in 1782, in his eighty-fourth year.

James Watt, his eldest son, and only surviving child, was born at Greenock, the 19th January 1736. He received the rudiments of his education in the public schools of his native town; but, from the extreme delicacy of his constitution, was with difficulty enabled to attend the classes, and owed much of his acquirements to his studious habits at home. Little more is known of his early years, than that, from the first, he manifested a partiality for mechanical contrivances and operations, and frequently employed himself in that way. The desire of improvement in an art then little practised in Scotland, induced him to go to London in his eighteenth year, and there to place himself under the tuition of a mathematical instrument maker; but he remained little more than a twelvemonth, the infirm state of his health compelling his return to his paternal roof.

In that short period, he appears to have made great proficiency, and he continued, after his return to Scotland, to perfect himself in this art, both at home and on his visits to his mother's relations at Glasgow, where it was his wish to establish himself. But some opposition being made by the corporations, who considered him as an intruder upon their privileges, the professors of the university took him under their protection, and accommodated him with an apartment and premises for carrying on his business within their precincts, with the title and office of *mathematical instrument maker to the university*. This took place in 1757, when he was twenty-one years of age, and it must be inferred, that he had already given satisfactory proofs of talent to the eminent men who then adorned that seat of learning; of whom it is sufficient to mention the names of Robert Simson, Adam Smith, Dr Black, and Dr Dick the professor of natural philosophy. There Mr Watt applied sedulously to business, and in the few intervals which its concerns and ill health allowed, cultivated those various talents which distinguished him in after life; and there a lasting friendship was formed with the kindred minds of Dr Black, and of Mr, afterwards Dr Robison, then a student at the university, and nearly of his own age. He remained in the college until some time in the year 1763, when he removed into the town previously to his marriage with his cousin, Miss Miller, which took place in the summer of the following year.

The steam-engine had been a frequent subject of conversation between Mr Robison and himself, and the former had suggested the possibility of its application to the moving of wheel-carriages. About the year 1761 or 1762, Mr Watt had tried some experiments on the force of steam in a Papin's digester, and had constructed and worked with strong steam a small model, consisting of an inverted syringe, the bottom of the rod of which was loaded with a weight, alternately admitting the steam below the piston, and letting it off to the atmosphere. Observing the imperfections of this construction, he soon abandoned it; but the attention necessary to be bestowed upon his business prevented his reconsidering it, until the winter of 1763-4, when he was employed by the professor of natural philosophy to put in order a working model of a steam-engine upon Newcomen's construction. When he had repaired it and set it to work, he found that the boiler, though large in proportion to the cylinder, was barely able to supply it with steam for a few strokes per minute, and that a great quantity of injection-water was required, though it was but lightly loaded by the pump attached to it. It soon occurred that the cause lay in the little cylinder (two inches diameter, six inches stroke), exposing a greater surface to condense the steam than the cylinders of larger engines did, in proportion to their respective contents. By shortening the column of water in the pump, less steam and less injection-water were required, and the model worked at a proper speed. Thus the purpose for which it was put into his hands was accomplished; and with this mode of accounting for the defect, and this result, most artists would have been satisfied; but the case was different with Mr Watt. He had now become aware of a great consumption of steam, and his curiosity was excited to a more accurate investigation of the causes, in which he proceeded in a truly philosophical manner. The cylinder of his small model being of brass, he conceived that less steam would be condensed by substituting cylinders of some material which would transmit heat more slowly. He made a larger model, with a cylinder (six inches diameter, and one foot stroke) of wood soaked in oil and baked to dryness. He ascertained, from experiments made with boilers of various constructions, that the evaporation of boiling water is neither in proportion to the evaporating surface, nor to the quantity of water, as had been supposed, but to the heat that enters it; and that the latter depended chiefly on the quantity of surface exposed to the action of the fire. He likewise determined the weight of coal required for the evaporation of any given quantity of water. Being convinced that there existed a great error in the statement which had been previously given of the bulk of water when converted into steam, he proceeded to examine that point by experiment, and discovered that water, converted into steam of the heat of boiling water, was expanded to 1800 times its bulk, or, as a rule for ready calculation, that a cubic inch of water produced a cubic foot of steam. He constructed a boiler to be applied to his model, which should show, by inspection, the quantity of water evaporated, and consequently would enable him to calculate the quantity of steam used in every stroke of the engine. This he now proved to be several times the full of the cylinder. He also observed, that all attempts to improve the vacuum, by throwing in more injection-water, caused a disproportionate waste of steam; and it occurred to him that the cause of this was the boiling of water in vacuo at very low heats (recently determined, by Dr Cullen, to be under 100°); consequently, at greater heats, the injection-water was converted into steam in the cylinder, and resisted the descent of the piston. He now perceived clearly, that the great waste of steam proceeded from its being chilled and condensed by the coldness of the cylinder before it was sufficiently heated to retain it in an elastic state; and that, to derive the greatest advantage, the cylinder should always be kept as hot as the steam which entered it, and that, when the steam was condensed, it should be cooled down to 100°, or lower, in order to make the vacuum complete. Early in 1765, the fortunate thought occurred to him of accomplishing this by condensing the steam in a separate vessel, exhausted of air, and kept cool by injection, between which and the cylinder a communication was to be opened every time steam was to be condensed, while the cylinder itself was to be kept constantly hot. No sooner had this occurred to him, than the means of effecting it presented themselves in rapid succession. These in a great measure have already been described in the present work. A model was constructed, and the experiments made with it placed the correctness of the theory, and the advantages of the invention, beyond the reach of doubt.

In the course of these trials he was much struck by the great heat communicated to the injection-water by a small quantity of steam; and he proceeded by a very simple experiment to satisfy himself upon that subject, when he discovered that water converted into steam will heat about six times its own weight of water at 47° or 48° to 212°. He mentioned this extraordinary fact to Dr Black, who then explained to him his doctrine of latent heat, to the support of which Mr Watt had afterwards the satisfaction of contributing his experiments. From some of these he was led to suppose the latent heat of steam to be above 1000°, but he afterwards considered 960° a more accurate determination. From others, he deduced the important conclusion, that the sum of the latent and sensible heat of steam, at different temperatures, is a constant quantity, the latent heat increasing as the sensible heat diminishes; or, in other words, that a given weight of water in the state of steam contains nearly the same quantity of heat, whatever may be the bulk or density of the steam.

He also, at this time, made experiments upon the capacities of different bodies for heat, and upon the heats at which water boils under various pressures; from which he ascertained, that where the heats proceeded in an arithmetical ratio the elasticities proceeded in a geometrical ratio, the curve of which he laid down. These he repeated some years after with more accuracy.

We have been thus minute in our details of the successive steps by which Mr Watt proceeded to his great improvement upon the principle of the steam-engine, in order to convey some idea of the sagacity, ingenuity, and science, with which he conducted the investigation. Our limits will oblige us to be more brief in our narrative of his subsequent improvements.

From this period (the early part of 1765), his mind became very much engaged in contriving the machinery for executing his improvement upon a large scale; but the want of funds prevented his attempting it, until he was induced to address himself to Dr Roebuck, who had a short time before completed his establishment of the Carron Iron-works, and who, in addition to his known qualities of ingenuity and enterprise, was considered to be possessed of ample means of introducing the invention to the public. He agreed to enter into the plan, upon having the proceeds of two thirds of the invention assigned to him; and an engine upon a large scale was then constructed by Mr Watt, at Kinneill, near Borrowstounness, where the doctor then resided; the trials made with which gave satisfaction. But the introduction of the invention to the public was retarded, on the one hand, by the pecuniary difficulties in which the doctor became involved, by the failure of several of his multifarious undertakings; and, on the other, by the employment which the rising reputation of Mr Watt, for knowledge and skill in the line of a civil engineer, procured him.

He was employed in 1767 to make a survey for a canal of junction between the rivers Forth and Clyde, by what was called the Lomond Passage, and attended parliament on the part of the subscribers, where the bill was lost. An offer was then made to him of undertaking the survey and estimate of an intended canal from the Monkland Collieries to Glasgow; and these proving satisfactory, the superintendence of the execution was confided to him. This was quickly followed by his being employed by the Trustees for Fisheries and Manufactures in Scotland, to make a survey of a canal from Perth to Forfar, through Strathmore; and soon afterwards by the Commissioners of the Annexed Estates, to furnish a report and estimate of the relative advantages of opening a communication between the Firth of Clyde and the Western Ocean, by means of a navigable canal across the isthmus of Crinan,[1] or that of Tarbert. Business of this description now crowded upon him; and surveys, plans, and estimates, were successively undertaken by him for the harbours of Ayr, Port-Glasgow, and Greenock; the deepening of the river Clyde; the rendering navigable the rivers Forth and Devon, and the water of Leven; the making of a canal from Machrihanish Bay to Campbeltown, and of another between the Grand Canal and the harbour of Borrowstounness; the building of bridges at Hamilton and at Rutherglen, &c. &c. In these surveys he made use of a new micrometer, and a machine for drawing in perspective, which he had invented to facilitate his operations. Our limits do not allow us to go into the details of his Reports, which are remarkable for their perspicuity and accuracy, although the work of a self-taught engineer. The last and greatest work upon which he was employed was the survey and estimate of the line of a canal between Fort-William and Inverness, since executed by Mr Telford upon a larger scale than was at that time proposed, under the name of the Caledonian Canal.

Whilst engaged upon this survey, in the latter part of the year 1773, Mr Watt received the account of the death of his affectionate wife, who left him a daughter and a son. He appears soon after to have made up his mind to adopt the advice of his friend Dr Small of Birmingham, and the invitation of Mr Boulton, to settle in England. He had secured his title to his Improvements for saving Steam and Fuel in Fire-Engines, by patent, in the year 1769; but all hopes of carrying them into effect by the assistance of Dr Roebuck being at an end, he had induced that gentleman to agree, for certain considerations, to transfer his share of the patent to Mr Boulton of Soho, near Birmingham; a gentleman equally distinguished by his knowledge of the arts and his enterprising spirit, who had some years before established his manufactory upon a scale as unrivalled for extent and elegance as for the variety and perfection of the processes carried on. In conjunction with him, an application was made to parliament for an extension of the term of the patent, and an act prolonging it for twenty-five years was obtained in the year 1775, when the business of making steam-engines was commenced by the firm of Boulton and Watt.

Mr Watt now married for his second wife Miss Macgrigor, the daughter of an old friend at Glasgow, and devoted himself to the improvement of the details of the engine with a degree of application and exertion not to be expected from his delicate and infirm state of health; and he found in his partner a zealous and able coadjutor. Some engines for pumping water were soon made upon a large scale, and the savings in fuel were demonstrated by repeated comparative trials to amount to three fourths of the quantity consumed by those of the best construction previously in use. A deputation from the mining interest of Cornwall was sent to ascertain the fact, and their report led to the introduction of the improved engines into that county, to which they have proved of such vast utility.

The immediate application of the powers of steam to giving a rotary motion to mills had formed an early object of Mr Watt's attention, and he had deeply considered the various means of effecting this. One method of producing a continued movement in one direction was by a steam-wheel, described in his patent of 1769. Various others of a similar kind suggested themselves to him, of some of which drawings and models were made; but the difficulty of rendering them steam and air tight, and the loss of power by friction, induced him to turn his thoughts to the adaptation of the reciprocating motion to the production of a continued regular rotary one. This he accomplished by a series of improvements, the exclusive property of which he secured by successive patents in the years 1781, 1782, 1784, and 1785, including, among other inventions the rotary motion of the sun and planet wheels,[1] the expansive principle, the double engine, the parallel motion, and the smokeless furnace. The application of the centrifugal regulating force of *the governer* gave the finishing stroke to the machine.

---

[1] The Crinan Canal was executed several years afterwards, under the direction of his friend Mr Rennie, with some variations.

The invention of the separate condenser, and the contrivances necessary to give it full effect, would alone have established the fame of Mr Watt; but when to these are added the various inventions called forth to perfect his rotative engines, we are impressed by a union of philosophical research, of physical skill, and of mechanical ingenuity, which has, we believe, no parallel in modern times. The perfection thus given to the rotative engine soon led to its general application for imparting motion to almost every species of mill-work and machinery, and gave an impulse, unexampled in the history of inventions, to the extension of our manufactures, wealth, and population.

Nor were Mr Watt's inventive powers confined to the steam-engine. The necessity of preserving accurate copies of his various drawings and of his letters, containing long and important calculations, and the desire of avoiding that labour himself, which he did not think it right to intrust to others, led him, in the year 1780, to contrive a copying apparatus, the exclusive property in which he secured by letters patent, and commenced the manufactory of them, in partnership with Mr Boulton and his friend Mr Keir, under the firm of James Watt and Company; a contrivance of great simplicity, and of which he reaped an ample benefit in the time, labour, and expense it saved to himself, to say nothing of its advantages to the public.

In the winter of 1784–5, he put up an apparatus for heating, by means of steam, the room in which he drew and wrote. The possibility of doing this had been suggested by Colonel Cooke in the Philosophical Transactions for 1745; but we know not whether this was known to Mr Watt when he made this first practical attempt, from which he deduced proportions of surface, &c., which afterwards served to guide his firm in the introduction of the process in larger buildings.

Chemical studies engaged much of his attention during his busiest time: and at the very period when he was most engaged in perfecting his rotative engines, and in managing a business become considerable, and, from its novelty, requiring close attention, he entered deeply into the investigations then in progress relative to the constitution and properties of the different gases. Early in 1783, he was led, by the experiments of his friend and neighbour Dr Priestley, to the important conclusion, that water is a compound of dephlogisticated and inflammable airs (as they were then called) deprived of their latent or elementary heat, and he was the first to make known this theory. This was done in a letter to Dr Priestley, dated the 28th April 1783, in which he states the doctor's experiments to have come in aid of some prior notions of his own, and supports his conclusions by original experiments. That letter Dr Priestley received in London; and, after showing it to several members of the Royal Society, he delivered it to Sir Joseph Banks, with a request that it might be read at some of the public meetings of the society; but before that could be complied with, Mr Watt, having heard of some new experiments made by Dr Priestley, begged that the reading might be delayed. Those new experiments soon afterwards proved to have been delusive; and Mr Watt sent a revised edition of his letter to M. de Luc on the 26th November of the same year, which was not read to the society until the 29th April 1784, and appears in the Philosophical Transactions for that year, under the title of "Thoughts on the constituent Parts of Water and of Dephlogisticated Air, with an Account of some Experiments upon that subject." In the interim, on the 15th January 1784, a paper by Mr Cavendish had been read, containing his "Experiments on the Combustion of the Dephlogisticated and Inflammable Airs," and drawing the same inference as Mr Watt, with this difference only, that he did not admit elementary heat into his explanation. He refers in it to his knowledge of Mr Watt's paper, and states his own experiments to have been made in 1781, and mentioned to Dr Priestley: but he does not say at what period he formed his conclusions; he only mentions that a friend of his had in the summer of 1783 given M. Lavoisier some account of his experiments, as well as of the conclusion drawn from them. It is quite certain that Mr Watt had never heard of them; and Dr Blagden has stated, that he mentioned at Paris the opinions of both the English philosophers, which were not admitted without hesitation, nor until the French chemists had satisfied themselves by experiments of their own.[2]

Mr Watt also has the merit of being the first person to introduce into this country, and to carry into effect, on a practical scale, in any country, the bleaching of linens and cottons by oxymuriatic acid, the invention of his friend M. Berthollet. That gentleman had communicated his invention to Mr Watt at Paris in the winter of 1786-7, whither he had proceeded with Mr Boulton, at the instance of the French government, to suggest improvements in the mode of raising water at Marly; and his mind was instantly alive to the extensive application of which it admitted. He advised M. Berthollet to secure the property by an English patent; but that he declined, and left his friend to make such use of it as he thought proper. He, in consequence, communicated it to his father-in-law Mr Macgrigor, and gave directions for the construction of the proper vessels and machinery; and soon afterwards he himself superintended the first trials at his bleachfield near Glasgow, which proved eminently successful.

Some years after this, Mr Watt was led, by the illness of the daughter, and some apprehensions entertained for the son, who were the issue of his second marriage, to consider the subject of the medical application of the factitious airs, and to contrive various apparatuses for that purpose, which were described by himself, in his friend Dr Beddoes's publications on Pneumatic Medicine.

We have not space to particularise other improvements introduced by Mr Watt, or at his suggestion, into various arts; for there were few arts with the details of which he was not intimately acquainted, and to the practical professors of which he was not able and willing to impart information. We shall only mention, that before he left Glasgow to settle in England, he had assisted some of his friends in the establishment of a pottery there, to the success of which his experiments and advice had greatly contributed, and in which he afterwards continued a partner. At a later period, he occupied himself much upon a composition having the transparency, and nearly the hardness, of marble, from which he had many casts. This promoted, if it did not create, a taste for sculpture and statuary, and led to his employing himself, during the last years of his life, in the contrivance of a machine for multiplying busts and other carved work, which he left in a very forward state.

---

[1] Mr Watt had originally intended to derive the rotary motion from the working-beam by means of a connecting rod and crank; but the workman employed to make the model communicated it to a neighbouring manufacturer, who took out a patent for it. This stimulated Mr Watt to the invention of other means of effecting the same object, of which five are described in his patent of 1781. He afterwards used the crank, which was indeed his own, when he saw occasion, in defiance of the patentee, who never troubled him.

[2] There is a confusion of dates in the accounts of this affair. Mr Watt's letter to M. de Luc in the Philosophical Transactions appears dated 26th November 1784, which is evidently an error of the press. Mr Cavendish, in his letter, read 15th January 1784, speaks of Mr Watt's paper "as lately read before the society," whereas the paper itself purports to have been read on the 29th April 1784. This we cannot explain.

Mr Watt did not escape the common lot of eminent men, that of meeting with pirates of his inventions, and detractors from his merit. The latter indeed were but few, and their efforts transitory; but the former were numerous, and in proportion to the benefits expected to arise from an evasion of the patent-dues claimed by Boulton and Watt; though these were established upon the liberal footing of receiving only one third of the savings of fuel compared with the best steam-engines previously in use. In consequence, the attention both of Mr Watt and Mr Boulton was greatly occupied, from the year 1792 to the year 1799, in defending their patent rights against numerous invaders, the principal of whom were supported by a portion of the mining interest of Cornwall, although the respectable part of it refused to concur in their measures. The admission of their respective sons into the partnership in 1794, infused vigour into their proceedings; and after repeated verdicts, establishing the novelty and utility of Mr Watt's inventions, the validity of his claim was finally confirmed in the year 1799 by the unanimous decision of all the judges of the Court of King's Bench.

In 1800, upon the expiration of the act of parliament passed in his favour, he withdrew from business, resigning his shares to his two sons, of whom the youngest, Mr Gregory Watt, died soon after, having given splendid proofs of literary and philosophical talents, and left a durable record of the latter in his paper on Basalt in the Philosophical Transactions. Mr Watt continued to the close of life to interest himself in the pursuits of his former associates, and to maintain an uninterrupted friendship with Mr Boulton, whom he survived several years.

On two occasions afterwards, in 1811 and 1812, he gave proofs of the undiminished powers of his mind in his former profession. In the one instance, he was induced, by his grateful recollections of his residence in Glasgow, to assist the proprietors of the water-works there with a plan for supplying the town with better water, by means of a suction-pipe with flexible joints, laid across the bottom of the Clyde, accompanied with instructions for insuring the supply of water on the opposite side; a plan which answered completely, and for which the proprietors presented him with a handsome memorial of their gratitude. In the other instance he was prevailed upon, by the earnest solicitation of the Lords Commissioners of the Admiralty, to attend a deputation of the Navy Board, and to give, with his friend Captain Huddart, and Mr J. Jessop, an opinion upon the works then carrying on at Sheerness dock-yard, and the further ones projected by Messrs Rennie and Whidby. On this occasion, he no less gratified the gentlemen associated with him, by the clearness of his general views, than by his knowledge of the details, and received the thanks of the Admiralty. In 1814, he yielded to the wishes of his friends in undertaking a revision of Professor Robison's articles on STEAM and STEAM-ENGINES in the Encyclopædia Britannica; and enriched them with valuable notes, containing his own experiments upon steam, and a short history of his principal improvements upon the engine itself.

His originally infirm health had been subjected to severe trials by the great exertions of his mind, during the period of carrying into execution his improvements on the steam-engine, and had with difficulty resisted the cares and anxieties attending upon business, and those created by the subtilties of the law, during the protracted proceedings of seven long years. There appears to have been an organic defect in his digestion, and its effects were intensely severe sick headaches; but by continual temperance, and good management of his constitution, which he treated with much medical skill, it improved as he advanced in years; and with faculties little impaired he reached his eighty-fourth year, when, after a short illness, rather of debility than of pain, he expired in the bosom of his family at his house at Heathfield, in the county of Stafford, on the 25th August 1819.

His remains are deposited in the chancel of the adjoining parochial church of Handsworth, near those of Mr Boulton. An excellent bust had been made of him some years before his death by Mr Chantrey; and a statue was afterwards finished by the same great artist, intended by filial piety to be placed upon his tomb, and to convey to distant ages a faithful representation of those features in which the lines of intense thought were blended with the mild expression of benevolence.

Mr Watt was elected a member of the Royal Society of Edinburgh in 1784, of the Royal Society of London in 1785, and a corresponding member of the Batavian Society in 1787. In 1806, the honorary degree of LL. D. was conferred upon him by the spontaneous and unanimous vote of the senate of the university of Glasgow; and in 1808, he was elected, first a corresponding, and afterwards a foreign member, of the Institute of France.

In this brief narrative of his long, busy, and useful life, we have endeavoured to confine ourselves to a statement of the principal facts, and shall now add the character drawn up soon after his death, by a distinguished writer, who knew him well, and enjoyed a large portion of his esteem.[1]

"It is with pain that we find ourselves called upon, so soon after the loss of Mr Playfair, to record the decease of another of our illustrious countrymen, and one to whom mankind has been still more largely indebted—Mr James Watt, the great improver of the steam-engine.

"This name fortunately needs no commemoration of ours; for he that bore it survived to see it crowned with undisputed and unenvied honours; and many generations will probably pass away before it shall have 'gathered all its fame.' We have said that Mr Watt was the great *improver* of the steam-engine; but, in truth, as to all that is admirable in its structure, or vast in its utility, he should rather be described as its *inventor*. It was by his inventions that its action was so regulated as to make it capable of being applied to the finest and most delicate manufactures, and its power so increased as to set weight and solidity at defiance. By his admirable contrivances, it has become a thing stupendous alike for its force and its flexibility—for the prodigious power which it can exert, and the ease, and precision, and ductility with which it can be varied, distributed, and applied. The trunk of an elephant that can pick up a pin or rend an oak is as nothing to it. It can engrave a seal, and crush masses of obdurate metal like wax before it,—draw out without breaking, a thread as fine as gossamer, and lift a ship of war like a bauble in the air. It can embroider muslin and forge anchors,—cut steel into ribbands, and impel loaded vessels against the fury of the winds and waves.

"It would be difficult to estimate the value of the benefits which these inventions have conferred upon the country. There is no branch of industry that has not been indebted to them; and in all the most material, they have not only widened most magnificently the field of its exertions, but multiplied a thousandfold the amount of its productions. It is our improved steam-engine that has fought the battles of Europe, and exalted and sustained, through the late tremendous contest, the political greatness of our land. It is the same great power which now enables us to pay the interest of our debt, and to maintain the arduous struggle in which we are still engaged, with the skill and capital of countries less oppressed with taxation. But these are poor and narrow views of its importance. It has increased indefinitely the mass of human comforts and enjoyments, and rendered cheap and accessible all over the world the materials of wealth and prosperity. It has armed the feeble hand of man, in short, with a power to which no limits can be assigned, completed the dominion of mind over the most refractory qualities of matter, and laid a sure foundation for all those future miracles of mechanic power which are to aid and reward the labours of after generations. It is to the genius of one man, too, that all this is mainly owing; and certainly no man ever before bestowed such a gift on his kind. The blessing is not only universal, but unbounded; and the fabled inventors of the plough and the loom, who were deified by the erring gratitude of their rude contemporaries, conferred less important benefits on mankind than the inventor of our present steam-engine.

---

[1] This article was written for and published in the *Supplement* to the preceding editions; the editor, as is stated in a note appended to it, being received it from a quarter entitling him to aver that it contains an accurate and faithful account of Mr Watt. It was written, in fact, by his son. The brilliant eulogium with which it concludes was written by Mr, now Lord Jeffrey. An admirable account of Mr Watt and his discoveries has lately been given to the world by M. Arago, of the National Institute of France.

"This will be the fame of Watt with future generations; and it is sufficient for his race and his country. But to those to whom he more immediately belonged, who lived in his society, and enjoyed his conversation, it is not perhaps the character in which he will be most frequently recalled—most deeply lamented—or even most highly admired. Independently of his great attainments in mechanics, Mr Watt was an extraordinary, and in many respects a wonderful man. Perhaps no individual in his age possessed so much and such varied and exact information,—had read so much, or remembered what he had read so accurately and well. He had infinite quickness of apprehension, a prodigious memory, and a certain rectifying and methodizing power of understanding, which extracted something precious out of all that was presented to it. His stores of miscellaneous knowledge were immense,—and yet less astonishing than the command he had at all times over them. It seemed as if every subject that was casually started in conversation with him, had been that which he had been last occupied in studying and exhausting; such was the copiousness, the precision, and the admirable clearness of the information which he poured out upon it without effort or hesitation. Nor was this promptitude and compass of knowledge confined in any degree to the studies connected with his ordinary pursuits. That he should have been minutely and extensively skilled in chemistry and the arts, and in most of the branches of physical science, might perhaps have been conjectured; but it could not have been inferred from his usual occupations, and probably is not generally known, that he was curiously learned in many branches of antiquity, metaphysics, medicine, and etymology, and perfectly at home in all the details of architecture, music, and law. He was well acquainted, too, with most of the modern languages, and familiar with their most recent literature. Nor was it at all extraordinary to hear the great mechanician and engineer detailing and expounding, for hours together, the metaphysical theories of the German logicians, or criticising the measures or the matter of the German poetry.

"His astonishing memory was aided, no doubt, in a great measure, by a still higher and rarer faculty—by his power of digesting and arranging in its proper place all the information he received, and of casting aside and rejecting, as it were instinctively, whatever was worthless or immaterial. Every conception that was suggested to his mind seemed instantly to take its place among its other rich furniture, and to be condensed into the smallest and most convenient form. He never appeared, therefore, to be at all encumbered or perplexed with the *verbiage* of the dull books he perused, or the idle talk to which he listened; but to have at once extracted, by a kind of intellectual alchemy, all that was worthy of attention, and to have reduced it, for his own use, to its true value and to its simplest form. And thus it often happened that a great deal more was learned from his brief and vigorous account of the theories and arguments of tedious writers, than an ordinary student could ever have derived from the most faithful study of the originals,—and that errors and absurdities became manifest from the mere clearness and plainness of his statement of them, which might have deluded and perplexed most of his hearers without that invaluable assistance.

"It is needless to say, that, with those vast resources, his conversation was at all times rich and instructive in no ordinary degree; but it was, if possible, still more pleasing than wise, and had all the charms of familiarity, with all the substantial treasures of knowledge. No man could be more social in his spirit, less assuming or fastidious in his manners, or more kind and indulgent towards all who approached him. He rather liked to talk, at least in his later years; but though he took a considerable share of the conversation, he rarely suggested the topics on which it was to turn, but readily and quietly took up whatever was presented by those around him, and astonished the idle and barren propounders of an ordinary theme, by the treasures which he drew from the mine they had unconsciously opened. He generally seemed indeed to have no choice or predilection for one subject of discourse rather than another; but allowed his mind, like a great cyclopædia, to be opened at any letter his associates might choose to turn up, and only endeavoured to select from his inexhaustible stores what might be best adapted to the taste of his present hearers. As to their capacity he gave himself no trouble; and indeed such was his singular talent for making all things plain, clear, and intelligible, that scarcely any one could be aware of such a deficiency in his presence. His talk, too, though overflowing with information, had no resemblance to lecturing or solemn discoursing, but, on the contrary, was full of colloquial spirit and pleasantry. He had a certain quiet and grave humour, which ran through most of his conversation, and a vein of temperate jocularity, which gave infinite zest and effect to the condensed and inexhaustible information which formed its main staple and characteristic. There was a little air of affected testiness, and a tone of pretended rebuke and contradiction, with which he used to address his younger friends, that was always felt by them as an endearing mark of his kindness and familiarity—and prized, accordingly, far beyond all the solemn compliments that ever proceeded from the lips of authority. His voice was deep and powerful, though he commonly spoke in a low and somewhat monotonous tone, which harmonized admirably with the weight and brevity of his observations, and set off to the greatest advantage the pleasant anecdotes which he delivered with the same grave brow and the same calm smile playing soberly on his lips. There was nothing of effort, indeed, or impatience, any more than of pride or levity, in his demeanour; and there was a finer expression of reposing strength and mild self-possession in his manner, than we ever recollect to have met with in any other person. He had in his character the utmost abhorrence for all sorts of forwardness, parade, and pretension; and indeed never failed to put all such impostors out of countenance, by the manly plainness and honest intrepidity of his language and deportment.

"In his temper and dispositions he was not only kind and affectionate, but generous, and considerate of the feelings of all around him, and gave the most liberal assistance and encouragement to all young persons who showed any indications of talent, or applied to him for patronage or advice. His health, which was delicate from his youth upwards, seemed to become firmer as he advanced in years; and he preserved, up almost to the last moment of his existence, not only the full command of his extraordinary intellect, but all the alacrity of spirit and the social gaiety which had illuminated his happiest days. His friends in this part of the country never saw him more full of intellectual vigour and colloquial animation, never more delightful or more instructive, than in his last visit to Scotland in autumn 1817. Indeed it was after that time that he applied himself, with all the ardour of early life, to the invention of a machine for mechanically copying all sorts of sculpture and statuary, and distributed among his friends some of its earliest performances, as the productions of a young artist just entering on his eighty-third year.

"This happy and useful life came at last to a gentle close. He had suffered some inconvenience through the summer; but was not seriously indisposed till within a few weeks from his death. He then became perfectly aware of the event which was approaching; and, with his usual tranquillity and benevolence of nature, seemed only anxious to point out to the friends around him the many sources of consolation which were afforded by the circumstances under which it was about to take place. He expressed his sincere gratitude to Providence for the length of days with which he had been blessed, and his exemption from most of the infirmities of age, as well as for the calm and cheerful evening of life that he had been permitted to enjoy, after the honourable labours of the day had been concluded. And thus, full of years and honours, in all calmness and tranquillity, he yielded up his soul without pang or struggle, and passed from the bosom of his family to that of his God!

"He was twice married, but has left no issue but one son, long associated with him in his business and studies, and two grandchildren by a daughter who predeceased him. He was a fellow of the Royal Societies both of London and Edinburgh, and one of the few Englishmen who were elected members of the National Institute of France. All men of learning and science were his cordial friends; and such was the influence of his mild character, and perfect fairness and liberality, even upon the pretenders to these accomplishments, that he lived to disarm even envy itself, and died, we verily believe, without a single enemy."

WATTS, Isaac, D. D., a learned and eminent dissenting minister, was born at Southampton in 1674, of parents eminent for piety, and considerable sufferers for conscience-sake. In 1690 he was sent up to London for academical education under the tuition of the Rev. Thomas Rowe; and in 1696 was himself engaged as tutor to the son of Sir John Hartopp, Bart. at Stoke Newington. He began to preach in 1698, and met with general acceptance; and after officiating as an assistant to the Rev. Dr Isaac Chauncy, he succeeded in his pastoral charge in 1702, and continued to preside over that church as long as he lived. Though his whole income did not amount to a hundred a year, he allotted one third of it to the poor. He died in 1748. His numerous works have rendered his name famous among people of every denomination, both in this and other countries, and have been translated into a variety of languages. His Lyric Poems, his Psalms and Hymns, and his Divine Songs for Children, have had an amazing number of editions. His logic and philosophy have been much admired. He also wrote works upon a variety of other subjects, and printed several volumes of his sermons. He was admired for the mildness and benevolence of his disposition. After his death, his Works were collected, and published in six volumes quarto.

WAUFGORN, a town of Hindustan, province of Aurungabad, twenty-four miles north from Poonah, whence originated the Holcar family.

WAUGUR, an extensive district of Hindustan, province of Gujerat, tributary to the Guicowar. It is intersected by the river Mahy.

WAUJPORE, a town of Hindustan, province of Gujerat, forty-five miles from Surat. Long. 73. 47. E. Lat. 21. 2 N.

WAUSSIM, a town of Hindustan, province of Berar, situated on a small stream which falls into the Wurdah. Long. 77. 28. E. Lat. 20. 10. N.

WAVE, in *Philosophy*, water, or any other fluid, raised above the general level of the surface.

The waves of the sea are of two kinds, natural and accidental. The natural waves are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves are those occasioned by the wind's re-acting upon itself by repercussion from hills and mountains, or high shores, and by the dashing of the waves themselves, otherwise of the natural wind, against rocks and shoals: all these causes give the waves an elevation which they can never have in their natural state.

WAWUL, a village of Hindustan, province of Gujerat, situated on the Sereswati, a few miles to the south-east of Radunpoor. It contains about 300 houses.

WAX, or *Bees' Wax*, in *Natural History*, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the pollen of flowers.

The best sort is that of a lively yellow colour, and an agreeable smell, somewhat like that of honey. When new, it is toughish, yet easy to break; but by age it becomes harder and more brittle, loses its fine colour, and in a great measure its smell.

It appears that wax and the pollen have for their basis a fat oil which passes to the state of resin by its combination with oxygen. If the nitric or muriatic acid be digested upon fixed oil for several months, it passes to a state resembling wax. Wax, by repeated distillations, affords an oil which possesses all the properties of volatile oils. It is reduced into water and carbonic acid by combustion. The colouring matter of wax is insoluble in water and in alcohol.

Fixed alkalies dissolve wax, and render it soluble in water. It is this saponaceous solution which forms the punic wax. It may be used as the basis of several colours, and may be made into an excellent paste for washing the hands. Ammoniac likewise dissolves it; and as this solvent is evaporable, it ought to be preferred when it is proposed to use the wax as a varnish.

Way.

From the common yellow wax, by bleaching, is formed white wax, sometimes called, very improperly, *virgin-wax*. The greater the surface is in proportion to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water. When melted, they press it through a strainer of tolerably fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with water, and often turning it: by this means it soon becomes white. The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use both in medicine and in many of the arts and manufactures. It has sometimes been given internally in dysenteries and erosions of the intestines; but its great use is in the making of ointments and plasters, and the greater part of those of the shops owe their consistence to it. The white wax is also an ingredient in some of the cerates and ointments of the shops; and it is used in making candles, and in many of the nicer arts and manufactures where wax is required.

Sealing-Wax, or *Spanish Wax*, is a composition of gum-lac, melted and prepared with resins, and coloured with some suitable pigment. There are two kinds of sealing-wax in use; the one hard, intended for sealing letters, and other such purposes; the other soft, designed for receiving the impressions of seals of office to charters, patents, and such written instruments. The best hard red sealing-wax is made by mixing two parts of shell-lac, well powdered, and resin and vermilion, powdered, of each one part, and melting this combined powder over a gentle fire; and when the ingredients seem thoroughly incorporated, working the wax into sticks. Seed-lac may be substituted for the shell-lac; and instead of resin, boiled Venice turpentine may be used. A coarser hard red sealing-wax may be made by mixing two parts of resin and of shell-lac, or vermilion and red lead, mixed in the proportion of one part of the vermilion to two of the red lead, of each one part, and proceeding as in the former preparation. For a cheaper kind, the vermilion may be omitted, and the shell-lac also for very coarse uses. Wax of other colours is made by substituting other colouring matters for vermilion, as verditer for blue, ivory black for black wax. For uncoloured soft sealing-wax, take of bees' wax one pound, of turpentine three ounces, and of olive oil one ounce; place them in a proper vessel over the fire, and let them boil for some time; and the wax will then be fit to be formed into rolls or cakes for use. For red, black, green, blue, yellow, and purple soft sealing-wax, add to the preceding composition an ounce or more of any ingredients directed above for colouring the hard sealing-wax, and stir the mass till the colouring ingredients be incorporated with the wax.

WAY, a passage or road. The Roman ways were divided into consular, prætorian, military, and public; and of these we have four remarkable ones in England. The first is *Watling Street* or *Watheling Street*, leading from Dover to London, Dunstable, Towcester, Atherston, and the Severn, extending as far as Anglesea in Wales. The second, called *Hikenild* or *Ikenild Street*, stretches from Southampton over the river Isis at Newbridge; thence by Camden and Litchfield; then passes the Derwent near Derby, and ends at Tynemouth. The third, called *Fosse-way*, because in some places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonshire, by Tethbury, near Stow in the Wold, and beside Coventry, to

Leicester, Newark, and so to Lincoln. The fourth, called *Erming* or *Erminage Street*, extends from St David's, in Wales, to Southampton.

WAYGHTES, or WAITS, a word which is used only in the plural number, and signifies *hautboys*. It is now applied to the performers on these and other musical instruments, by a transition from the instruments themselves, and particularly to those performers who parade the streets by night, about the Christmas season of the year.

WAYGIOU. See WAGEEO.

WAYTE, a rocky island in the Straits of Macassar, near the west coast of Celebes. Long. 119. 18. E. Lat. 0. 40. S.

WAYWODE is a title formerly given to the governors of the chief places in the dominions of the czar of Muscovy. The palatines or governors of provinces in Poland also bore the quality of *waywodes* or *waiwodes*. The Poles likewise called the princes of Wallachia and Moldavia *waywodes*, as esteeming them no other than on the footing of governors, pretending that Wallachia and Moldavia are provinces of Poland. Everywhere else these are called *hospodars*. Du Cange says, that the name *waywode* is used in Dalmatia, Croatia, and Hungary, for a general of an army; and Leunclavius, in his Pandects of Turkey, tells us it usually signifies *captain* or *commander*.

WEARY BAY, on the north-east coast of New Holland, south of Endeavour River.

WEATHER. The term *weather* is used, in the popular sense which is commonly attached to the word, to express the general condition of the atmosphere resulting from heat or cold, tranquillity or commotion, dryness or humidity, in all its modifications of visible and invisible vapour, together with the other variable phenomena accompanying the meteorological changes which are exhibited in ceaseless rotation by that great mass of attenuated matter. There being no department of physical inquiry where the desire of knowledge and the gratification of a rational curiosity is so constantly and inseparably connected with our personal comfort, the state of the weather has, in all ages and in every country, occupied a large share of the attention of naturalists, as well as of ordinary observers. It is not a little remarkable, however, that notwithstanding the general interest which the subject is fitted to excite, and the constant attention that has been devoted to it, there is no branch of science in which, with all the advantages of accurate instruments and accumulated observations, there is less of systematic and well-established principles, or more of arrogant and unfounded pretension. This must be ascribed, not so much to the defective state of our knowledge concerning the actual condition of that portion of the atmosphere which is within the immediate sphere of our observation, as to the fact that the causes which contribute to produce changes in the meteorological phenomena which it exhibits in some particular geographical situation, frequently have their origin in regions far beyond the reach of the observer; and hence predictions respecting the state of the weather must be founded more upon conjectures suggested by a cautious induction than upon the indications of instruments which, however well fitted to give precise and accurate information respecting the condition of the surrounding air with regard to pressure, temperature, or humidity, furnish no means of discovering the remote causes by which that condition was produced, or may be afterwards affected and even entirely subverted.

It may be hoped, however, that the efforts which have been lately made for the erection of magnetic and meteorological observatories in almost every important station of the globe, and the liberal encouragement which has been granted by the various governments of Europe for supplying these establishments with suitable instruments, under the superintendence of skilful observers, will, at no distant period, furnish precise and accurate data for determining the simultaneous condition of the atmosphere over an extensive portion of the surface of the earth, and thus enabling us to ascertain whether the meteorological appearances which distinguish different seasons are altogether of an anomalous character; or, otherwise, to what extent they are, like other physical phenomena, the result of fixed and invariable laws, which, though involved in obscurity as to their mode of action, do not fail, after a certain lapse of time, to display their operation by the periodical revolutions in the weather, to which they give birth.

Though this country can scarcely claim the honour of having first set the example to other states, of engaging with zeal and alacrity in this great and important undertaking, it must be admitted that the British Association for the Advancement of Science has contributed in no small degree to draw the attention of other learned bodies to the subject, while it has annually devoted a considerable portion of its funds to the investigation of objects which are calculated to throw great light upon the leading principles of meteorology. At the recommendation of that institution, the British government has established magnetic and meteorological observatories at various places in the empire, as well as in the colonies, particularly at Greenwich, Dublin, Plymouth, the Cape of Good Hope, Van Diemen's Land, Madras, Sincapore, Simla in the Himalaya range, Aden in the Arabian Gulf, and Toronto in Canada. It has also furnished instruments to the observatories established at Breslau in Prussia, at Hammerfest in Norway, as well as to those established at Cairo and at Algiers. The liberal and enlightened views evinced by the British government for the support of these institutions have been followed by corresponding efforts on the part of other civilized states; and accordingly we learn that establishments for similar purposes are now fixed at St Petersburg, Kasan, Catherinebourg, Barnaoul, Nicolaieff, and various other places in the Russian empire, as well as at Berlin, Brussels, Copenhagen, Göttingen, Gotha, Hanover, Heidelberg, Leipzig, Milan, Munich, Philadelphia, Prague, Upsala, &c.

It is only by the co-operation of numerous observers pursuing with regularity and perseverance a system of judicious observations, at stations so remote from each other, that we can obtain, in the first place, an accurate register of the meteorological phenomena which are connected with geographical position, and be afterwards enabled to apply suitable equations to the general laws by which these phenomena are regulated, for the purpose of adapting them to the local peculiarities which distinguish the climates of particular places. Many years may be necessary for the full development of these laws; but already have the magnetic observations recorded at stations separated widely by distance indicated the existence and operation of a diffusive principle, probably of a thermo-electric character, which, exerting its influence in the bowels of the earth, is capable of producing contemporaneous magnetic effects of the most palpable kind at the surface. The relation subsisting between caloric and the distribution of the electric fluid may lead us to expect from these observations new discoveries respecting the mysterious laws which govern the periodical and secular changes of terrestrial temperature that have so long perplexed geologists, and may thus authorize us to anticipate some of the great thermal revolutions to which our globe is from time to time exposed. For further information on this subject, the reader may consult the articles BAROMETER, CLIMATE, CLOUDS, COLD, EVAPORATION, HYGROMETRY, METEOROLOGY, TEMPERATURE. (V. V. V.)

WEAVING.

Weaving is the art of arranging yarn or thread of various materials, flax, cotton, wool, silk, &c., so as to form cloth. In all woven cloths, of whatsoever material, one system of threads is made to pass alternately under and over another system of threads, so as to resemble, when held up to the light, a piece of close net-work.

Though, for the sake of effecting this in less time, and with less labour, than common instruments are capable of, steam power, and somewhat complicated machinery, have been resorted to, a very simple contrivance is all that is absolutely necessary to accomplish the object. The threads, which run longitudinally, or from end to end of the piece, and which are called the warp, or, among the silk-weavers, the chaine (from *la chaine*, Fr.), must be arranged evenly side by side. There must then be some contrivance, first, to raise every alternate thread, and therefore half the threads which form the warp; second, to pass the thread which forms the weft between the alternate threads so raised; and, lastly, to strike home the thread of weft so passed through. The process is then repeated by depressing the half of the threads previously raised, and raising the half previously depressed; by again passing the weft through and striking it home; and so on until the whole warp is completely wefted. The instrument for effecting this is called a loom, the different improvements of which we shall hereafter describe.

The art of weaving was probably known before that of spinning. Many of the rude nations with which we have become acquainted, even within the last century, have practised the former, while they have been completely ignorant of the latter. The fibrous parts of many plants, and even the bark of some trees, afford a thread which barbarous nations know how to weave into a species of matting. Specimens of this kind of weaving—for such it must be deemed, though perhaps not produced by the loom—are to be found in the British Museum; and the mats of the New Zealanders, made from what has been called the New Zealand flax (*phormium tenax*), are of this character. Nay even the most savage nations seem to have known how to avail themselves of the felting property of wool before even the knowledge of weaving. (Wool, and its Manufactures.) Other substances are also made to cohere together, apparently after being reduced to a pulp, as in the manufacture of paper. We have before us a New Zealand production of this character, made of the fibre of the phormium tenax; but the matting to which we have alluded must be familiar to every reader of any one of the instructive compilations of voyages among barbarous nations; books which are now happily multiplied at a very moderate price, and in every variety of form.

The art of weaving from spun yarn is of very remote antiquity. In the linen cloths in which the mummies are enveloped, we have specimens of one of the woven fabrics of ancient Egypt. From the nations of the east, a knowledge of weaving gradually spread to the west, where it has rapidly improved; while in the east it remains nearly where it was in the most ancient times; and the very perfect state of the manufacture shows with what rude instruments it is possible to produce the most perfect plain fabrics.

It is difficult to say when the art of weaving found its way into this country. Cæsar states that it was not known when he invaded the island. This however has been contradicted, though we are at a loss to know on what authority. It is probably from a mere inference, that as the Gauls introduced other arts into Britain, they may have introduced the art of weaving from spun yarn. As for the mere art of matting, that was probably practised by them as we find it among all barbarous nations.

Among the Romans, when they invaded Britain, the manufactures of cloth and linen were in great perfection, and it is well known that they had a manufactory at Winchester; but it does not appear that in the Saxon times manufactures were much attended to. A specimen of very ancient manufacture is still preserved in the cathedral of Bayeux. It is a web of linen sixty-seven yards long, embroidered with a history of the conquest of England by William the Norman, commencing with Harold's embassy, and ending with the battle of Hastings and Harold's death in 1066. This specimen of ancient art is supposed to have been executed by Matilda, the wife of the conqueror; but although it may have been embroidered in England, the cloth on which the figures are wrought was probably the production of some other country.

After the Norman invasion, manufactures seem to have sprung up in England, having probably met with some encouragement from the conqueror; and this seems the more probable, from the fact that the business of manufactures was for many centuries chiefly in the hands of foreigners. For two or three centuries after the conquest, the only records to be found of manufactures consist in the preambles of antiquated statutes for the regulation of the trade in wool and woollens (See the article Wool, and its Manufactures); but even these only show that England was immeasurably behind her neighbours in ingenuity and skill; and it was not until the reign of Edward III. that the encouragement of foreign artisans was systematically attended to. By that monarch, direct encouragement was given to foreign weavers and cloth-workers; and the establishment of some Brabant weavers, who settled in York, soon gave a great reputation to that city.

But that which promoted the establishment of manufactures in this country to a far greater extent than direct encouragement, was the persecutions to which, from time to time, the Flemish and French manufacturers were subjected. The persecution of the duke of Alva, for instance, in 1576, drove a large number of Flemish weavers to this country, who introduced the manufacture of baizes, serges, and crapes, in various parts of England; and the revocation of the edict of Nantes had the same effect in importing the silk manufacture into this country. It is said that the persecutions of Louis XIV. drove about 50,000 manufacturers to England.

A reference to the several articles on cotton, linen, silk, and woollen manufactures, will show the very remarkable manner in which our manufactures have grown up of late years; and it will at once be seen, that our present superiority is owing much more to improved methods of spinning than to any improvement in weaving. The steam or power-loom, though it is certainly very superior in its results to the common hand-loom, and still more so to the loom of the East Indies, does not exhibit that marked superiority which the mule does to the ancient spinning-wheel, or the still more ancient distaff. To the multiplication of the spindle in the form of the jenny, the throstle, and the mule, we are indebted for our pre-eminence in the cotton manufacture; and although great improvements are visible in every branch of our manufactures, the whole of these taken together do not constitute so complete a revolution as the improvements of Arkwright, Crompton, and Kelly, and the application of steam by Watt.

We have already shown how few and simple are the operations necessary to perfect weaving. The loom of the Hindu has been described in the article COTTON MANUFACTURES. In Baines's history of that branch of our industry are some characteristic figures of the Hindu manufacture in all its stages; and when it is considered that the muslins of the east have never been surpassed, the truth of the above proposition will at once be admitted. To perform the same operation equally well, but in less time and at a less cost, has always been deemed an object of sufficient importance to occupy the attention of men of superior intelligence and energy; and although much has been done within the last sixty or eighty years, there is still ample room for improvement.

The common European loom, which is one stage in advance of the rude loom of the Hindu, has been essentially the same for centuries. The loom itself indeed remains unaltered, and it is only in the mode of throwing the shuttle that any improvement has taken place. Of that improvement we shall presently speak.

The loom consists, first, of a strong frame-work of four upright posts, with beams at top from post to post, something like a four-post bedstead. It is further strengthened by two longitudinal pieces of wood, in which the posts rest, with two similar pieces about half way up, with cross pieces at each end. These form the frame-work of the loom, and it must be obvious that their arrangement is of little moment.

The essential parts of the loom consist of, 1st, the apparatus for stretching the warp; 2d, the simple contrivance for raising half the strings of the warp and depressing the other half, so as to open a space for the weft to be cast through; 3d, the instrument for casting the weft between the opened threads of the warp; and, 4th, that for striking it home.

At one end of the frame above described, is a beam called the warp-beam, round which the longitudinal yarns which form the warp are wound. This beam is, in some better made looms, a well-rounded roller, but in the looms generally in use, even at this time, it is but rudely rounded; it has, in fact, the appearance of an originally square beam, with the edges roughly taken off.

At the other end of the loom is another and corresponding beam, called the cloth-beam, on which the woven portion of the work is wound. This cloth-beam is generally more carefully constructed than the warp-beam. It is furnished with a rack-wheel, for the purpose of *letting in* or winding on the cloth, as portions of it become woven. This keeps it in a state of tension, with the aid of a pulley; sometimes an iron weight, but often a stone, slung over the warp-beam. As the web is wound on the cloth-beam, the unwoven warp is of course wound off the warp-beam, the whole being kept distended during the progress of the work.

We now come to the arrangement for raising the threads or yarns of the warp, half and half alternately. Slung across two pulleys at the top of the frame-work of the loom, are two pieces of wood, called, with the apparatus attached to them, heddles. These pieces of wood are of length just equal to the breadth of the cloth to be woven. If the warp consist of 100 yarns or threads, each of these heddles has fifty pieces of twine descending about a foot below the warp, with a loop or eye-let hole, through each of which a thread of the warp passes alternately. The hanging ends of these pieces of twine are attached to two pieces of wood similar to the heddles, and are made fast to two treadles, so that when one treadle is pressed down with the weaver's foot, half the yarns of the warp will be raised, and the others depressed, so as to give to the warp an opening which, on a side view, has the appearance of an elongated lozenge. This opening is called the *shed*, and should be about two inches between the yarns.

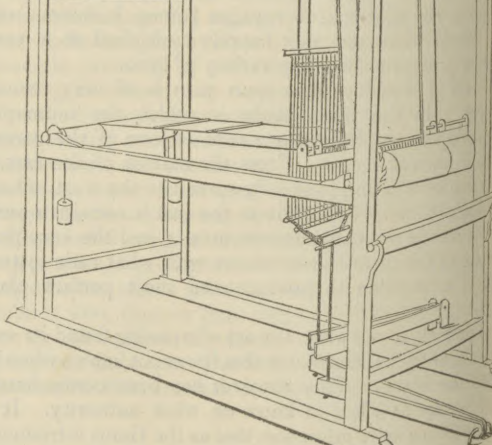
It is in the shuttle, the instrument for passing the weft between the opened warps, and the batten, or instrument for striking the weft home, that the great difference between the Hindu and the European loom consists. The Hindu shuttle was, and we believe still is, in form something like a long netting-needle; and when the weaver has passed the weft, the same instrument serves him to beat it home; but in the European loom they are distinct instruments, though intimately connected in the same portion of the loom. We shall now describe both.

The *batten*, which is also called the lay or lathe, consists of a moveable swing frame, suspended to a cross-bar resting easily upon the upper bars of the loom. From this cross beam descend two *swords*, as they are called, at the bottom of which is a sort of shelf, called the shuttle-race. The two ends of this shuttle-race are closed up at the sides, so as to form short troughs, in which two moveable pieces of wood, called pickers, or peckers, traverse along pieces of wire extending only the length of the two troughs, or each about one quarter of the length of the batten. To each of these two pickers is fastened a string, both strings loosely meeting at a handle which is held in the right hand of the weaver. When the shuttle is in one of the troughs, a smart jerk or pull at the picker projects the shuttle along the shuttle-race, and another sharp jerk or pull in the contrary direction projects it the other way. Formerly the shuttle was thrown by the hand, but about one hundred years ago, the picker, or fly-shuttle, was invented by one John Kay of Bury, in Lancashire; but it was opposed by the workmen, and not generally adopted for some time after. It nearly doubled the produce of a man's labour.

The *reed* is a frame with pieces of cane or wire fixed at equal distances upon the shuttle-race, and not unlike a comb in appearance. The canes or wires of the reed are called the *dents* (no doubt from the French *dents*, teeth); the yarns of the warp pass between them, and they serve to keep the work even, and to strike home the weft evenly. The reed is kept firmly in its place by a piece of wood fitting closely over it. This is called the cap or lay-cap, and the weaver, while working, holds it firmly grasped in his left hand.

The shuttle is a small piece of wood, pointed at each end, and hollowed in the middle, to contain the bobbin of yarn which is to form the weft. There is a small hole at the side of the shuttle called the eye, through which the yarn runs freely at each pick or jerk of the picker. On

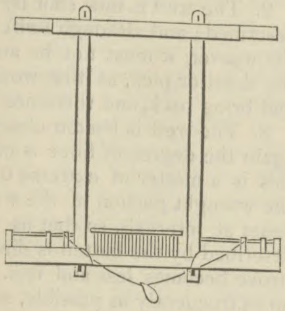
Fig. 1.



the under side of the shuttle are two small wheels, traversing very freely on their axes, on which the shuttle travels to and fro along the shuttle-race.

This description will be perfectly intelligible to the reader by an examination of the annexed cuts, which we need not encumber by reference marks, as they appear to us to be rendered unnecessary by the manner in which our description is divided. Figure 1 represents the loom, with the warp extended; fig. 2 is the batten, with the reed, the picker, and the shuttle-race; and fig. 3 is the shuttle.

Fig. 2.



Preliminary to the operation of weaving, there is much to be done in the way of preparation, which it is necessary that we should describe.

Fig. 3.

The yarn, as it comes from the spinner, whether intended for the warp or the weft, is usually in hanks of a known length. The yarn destined for the warp is wound off upon little spools of wood called bobbins. For this purpose the hank is placed upon a reel, from which it is wound upon the bobbin by a child.

The next process is that of warping, which is simply stretching the number of threads necessary to form the warp equally, and laying them parallel to each other. This is usually done by means of a warping mill, as it is usually called, which consists of two parts, namely, a vertical frame or rack in which the bobbins are placed, and the reel on to which the warp is wound. The vertical frame is constructed so as to allow about fifty bobbins to be so fixed as to revolve easily, and as to keep the yarn as it leaves the bobbin at equal distances. The several yarns are then brought to a focus, as it were, and made to pass through what is called a heck-box, whence it is wound round a large reel, so constructed in point of size as to gauge or measure off the warp. The reel is six feet in diameter and seven or eight in height, and is made to revolve by an endless rope passing round two wheels, one of which is turned by the warper. In order that the warp may be wound spirally on the reel, the heck-box, containing the rollers which guide the yarns, is made to rise and fall by a simple contrivance. It is made to slide up and down one of the upright supporters of the reel by being suspended from a cord, which, passing over a wheel or pulley, winds round the axle of the reel or is unwound, according to the way in which the reel is turned. One sixth part of the warp is usually wound off the bobbins at once. When the first portion of yarn is wound off, the clue or end of the yarns is crossed over pins projecting from the frame of the reel, and the reel is turned the reverse way, so that the yarn from the next set of bobbins descends by the descending motion of the heck-box, containing the guide-rollers. This process is repeated backwards and forwards until the whole warp is completed, when it is taken from the reel, and wound upon a stick into a bundle or large ball, the different doublings of the successive portions of the warp, as above described, forming separate crossings, in appearance not unlike a ball of lamp cotton on a gigantic scale. The equal portions of the warp aid the weaver in counting the yarns thereof.

Besides this division, the warp-mill makes another, which separates the yarns alternately, so as to facilitate their alternate arrangement in the geer or heddles. In the heck-box, as we have already explained, are the guide-pins, which conduct the yarns from the vertical frame to the reel. The operation of these pins it is almost impossible to understand distinctly without examination. The pins are inserted in two separate pieces of wood alternately. One piece of wood is raised by a handle for the purpose, which raises the alternate yarns. This occasions a space or division between the two sets of yarns, in which a wooden peg is placed. The other set of yarns is then raised by similar means, and the result is that the alternate yarns are crossed over the ends of the intermediate yarns. This is called the lease, and is carefully tied up so as to guide the weaver when he beams the warp.

In the state in which the warp is wound off the reel, as just described, it is delivered to the weaver; but before he winds it on to the warping beam, it must be sized. This consists in treating the warp with some glutinous solution, size or starch, for instance; the object being to render the yarns or threads of the warp smooth and even for wefting. This is done sometimes by the hand and sometimes by a machine. Generally it is dipped into the warm size, and squeezed by the hands and dipped again, until it is thoroughly soaked through. The machines in use merely imitate this process, the yarn being dipped and passed through rollers twice or thrice, by which the size or starch is introduced into the interstices of the yarn. It is then dried, in the case of woollen yarn, by being spread out in a field, and in other cases in a drying-house for the purpose. When thus sized, the yarn is ready for the loom.

The perfect equality of tension to which the warp is subjected in the loom, is of the greatest importance to the perfection of the cloth. If some of the yarns be looser than the rest, the cloth will be of unequal strength, and uneven to the eye, and its value will be less in proportion. The first operation towards extending the warp is framing or winding it on to the warp-beam: equality of tension much depends on skilful beaming. In order that the warp may be laid evenly on the beam, an instrument is used similar to the reel already described, except that it is not so fine. It is called a ravel or separator, and is composed of strips of cane fastened into a rail of wood, and secured at the upper part or extremities of the teeth by another piece of wood called the cape. This cape is moveable, and before it is put on, the yarns of the warp are passed between the teeth of the ravel, and the cape is put down to secure the yarns in their places. This being done, the warp is gradually and carefully wound upon the beam in the order in which it is destined to be wound off in the process of weaving.

In very broad goods, whether of cotton, linen, or woollen, the co-operation of several hands is necessary to the effecting of this process. Two persons must hold the ravel, one at least must watch the proper tension of the threads, and a fourth gradually turns the beam. In this the weavers aid each other.

The French weavers have an additional process, which certainly produces better beaming, and perhaps even saves time. Before passing the yarns through the ravel, the warp is wound from the bale on to a small reel: from this reel the yarns are drawn through the teeth of the ravel by the mere winding of the beam, equality of tension being preserved by a weight attached to the reel.

The warp being now upon the beam, every yarn has to be passed through a loop or eye of the heddles: this is called drawing. Two rods of wood are first inserted into what is called the lease, that is, the two crossings formed by the guide-pins of the warping mill, as already described. These rods are tied firmly together at the ends, the original ties are cast off, and the warp is spread out to its proper breadth. The effect of these lease-rods is to keep the alternate yarns which pass through one heddle from the intermediate yarns which pass through the other.

The warp-beam is suspended behind the heddles, and the passing of the yarns through the loops is done by two persons, the weaver and his assistant. The former, being in front of the heddles, opens the loops; and the latter, selecting the proper thread, which, as we have explained, cannot well be mistaken, delivers it to be drawn through the open loop or eye. This being done, the yarns are drawn through the reed by a hook called the reed-hook or sley. Two threads pass through each interval of the reed, the one below and the other above the warp: and in order to preserve this division, there is another rod of wood, which divides the warps into what are called *spitfuls*, the division being just the reverse of the lease-rods. By these several contrivances, the threads of the warp are so easily distinguished, that if one break in the course of weaving, a very common occurrence in the case of a break-warp, it is easily traced and taken up.

The accuracy of the lease being thus carefully preserved, the cords which move the heddles are attached. This is so arranged that the motion communicated by the heddle is continuous, that is, while one heddle is depressed, the other must be equally raised, so that the warp is opened equally, as already described. The reed is now attached to the lay or batten, and is kept firmly in its place by the cap, and the whole is so nicely hung as not to overstrain the weaver's arm in striking the weft home. An ill-poised batten creates great fatigue; and to avoid this, and perform its work effectually, it should be hung midway between the heddle and the woven portion of the work. The whole distance between the last woven shoot of the weft, called the *fall*, and the heddle, forms the space in which the batten describes its arc; and the greater it is, the harder the stroke. In light goods it is accordingly small, in heavy goods greater; and as this also in part depends upon the length of the *sword*, or pendulous portion of the batten, the whole must necessarily bear a proportion to the size of the loom. The loom for narrow and light goods is small in all its parts; the loom for broad and heavy goods is of course large and strong. Properly poised, the batten returns to its position by its own weight as soon as the stroke is made. All that now remains to be done is to knot the near ends of the warp into small portions, and to tie them to a shaft attached to the cloth-beam. The warp-beam being properly adjusted, and the due degree of tension being given to the warp lying thus evenly between the two beams, the weaver's operations may commence.

The weaving of coarse, light, narrow cottons, linens, and stuffs, is so extremely simple, that children are soon able to perform it; but the finer descriptions of fabrics require more skill, and it is only a very few that can become first-rate workmen. It has been calculated that out of 10,000 hand-loom weavers in Leeds and the clothing villages around, less than 150 were able to earn the very highest wages in the market; and the difference of skill and speed was so great, that of two weavers working together in the same factory, at the same kind of work, one earned nearly twice as much as the other. "One man having had a full average of good work, has made in these six months 16s. 4d. a week; the man on the next loom to him has earned in the same time, and with the same work, 24s. a week; the best weaver we have has earned, with not quite such good work, in the same time, 28s. a week. Here then we have a difference arising out of skill, strength, and diligence alone, excluding greater duration of labour, of nearly 50 per cent."[1]

The distinct operations performed by the weaver are as follows.

1. The treadle is pressed down by the foot, so as to raise one heddle and depress the other. This must be done with force duly proportioned to the work in the loom. Too strong a pressure on the treadle subjects the yarns of the warp to unnecessary friction, both from the heddles and the reed, and also to undue stress of the warp. The threads or yarns consequently break, and this is one of the great causes of delay, and of the small earnings of some weavers compared with others.

2. The weft is now shot by the jerk of the picker already described; and although swift wefting is a great object with the weaver, it must not be attained by the mere force of the shoot or pick, as that would cause the shuttle to recoil, and bring back, and therefore loosen the yarn of the weft.

3. The weft is beaten close by the batten or lay. Here again the degree of force is of the utmost importance, and this is a matter of extreme difficulty to regulate, because the wrought portion of the web is wound on to the cloth-beam at intervals, so that as the wefting proceeds, the arc described by the batten is diminished, and the force of the stroke becomes less and less. The cloth should be taken up as frequently as possible, so as to preserve the equality of the wefting.

A patent was obtained in 1803, for a simple method of continually turning round the cloth-beam as the work proceeded, so as to wind on or let in the cloth shoot by shoot, with every stroke of the batten. This was easily effected by a racket, fixed on the end of the cloth-beam, with a catch moved by the stroke of the batten by one tooth at a time. Such an apparatus is attached to every power-loom; but, strange to say, simple as it is, it has not been universally adopted among the hand-loom weavers.

Making allowance for the difference of force and nicety, all kinds of weaving are really the same in principle. Nay, even the most complicated figures depend chiefly on the number of yarns raised together, and the number depressed, while the power-loom has not one feature different from what we have described, except as regards the *source of motion*; a point which should be always kept in view.

In the progress of the work, some kinds of yarn, in addition to the dressing and sizing of the warp before it is tied in, require a further dressing as they stand in the loom. This dressing is not required by woollen warps, and is decidedly injurious to silk; but in the case of flax and cotton it is absolutely necessary, in order to lay the fibres close. It is composed of some glutinous substance, which is applied with a brush to that portion of the warp which lies between the heddles and the warp-beam. As the dressed portion of the yarn is wrought, the process must be repeated. Besides laying the fibres of the yarn, the dressing gives strength and tenacity, and greatly facilitates the operation of the batten. It diminishes friction, and renders the cloth, when finished, equal, even, and smooth.

Various substances have been recommended for dressing the warp, but they all consist of the farina of grain or potatoes, made into a gelatinous paste, similar to that used by bookbinders. An inconvenience to which this is liable arises from the hard and glassy substance it forms when dried; hence it must be applied only to so much of the warp as can be woven at once. Every weaver however has his own method of using the dressing, so as to remedy this difficulty. Some mix salt with the dressing, others apply grease as the warp is drying; indeed this last method is generally adopted to facilitate the process of weaving.

So important has the dressing of the warps been deemed, that it has been the subject of several patents. In 1799, Mr Foden recommended the addition of some powdered gypsum, alum, and sugar; and in 1801 Mr Wilks had a patent for a method of preparing the starch of potatoes. In 1800, Mr Stuart took out a patent for starching cotton yarn in the cop; and in 1805 Mr Peter Marsland obtained another patent for the same object, by subjecting the cops to the action of hot starch in an exhausted receiver, whereby the starch was made to penetrate to the very centre of the cops.

---

[1] Assistant Hand-Loom Commissioners' Reports. Chapman, part iii. p. 530.

ich fabrics as do not require dressing, silk and woollen, for nstance, require the yarn to be cleared from time to tin with a comb, in order to remove obstructions, which mi t impede their progress through the reed. The comb its removes many inequalities, but such as do not yield to are removed either by a pair of nippers or a pair of sci ors. In what the weavers call bad, that is, unequal wa s, this clearing takes up a considerable portion of their tim The inequality and weakness of a warp is a great evi as more time is occupied in clearing and tying than in eaving, and wages, already inadequate, are thereby ren ered insufficient to the support of life. Many kinds of brics, such, for instance, as the finer kinds of worsted go s, namely, double twilled shalloons, called by the Lon do shopkeepers "French merinoes," wildbores, &c. re qui picking after weaving, that is, going over the work wi a pair of steel nippers, and taking off knots, threads, an other imperfections left by the process of weaving. If e weaver do this for himself, as he often does, it will tak about one third as much time as the weaving; but thi s often done by the wife, and perhaps still more fre qu tly by the weaver and his wife together.[1]

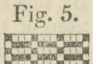
ch is the ordinary process of weaving in the common Br sh, or, more properly speaking, European loom, in wh a large proportion of the textile fabrics are still produ d.[2] It now remains to notice the contrivances for produ g figures, and the more modern improvement of substit ing steam for human power; an improvement which, as we ave already said, does not alter the nature of weaving, but erely regards the source of motion, and the method of mmunicating it, and of connecting the different motio to be produced, with one single source.

ried and complicated as figure-weaving is in practice, it i evertheless extremely simple in principle. We have see hat in plain weaving each yarn or thread of weft passes ove and under the threads of warp alternately, so that the sep ate crossings of the yarns form equilateral parallelogra s, or net-like squares. In the case supposed, we have ass ed one hundred warp yarns to be so arranged that eac pressure of the treadle raises the alternate fifty yarns, so at the result is a plain fabric, taking up eve alternate thread of warp. The threads, as have stated, will be arranged in squares, thu

Fig. 4.

w, suppose the two heddles, instead of taking up the alte ate threads of the warp, were so arranged that one of the took up three threads in succession, and the other onl ne, it would follow that the threads of weft would not app r equally exposed on the surface of the warp, but wou in some places pass over three threads, and others only one. The result would be a figu d face, as depicted in the annexed diagra The white portion of this figure represen the threads of warp, the black the threads of the wef covering one out of four and three out of four thre ls alternately. This variation of the number of thre ls of warp exposed is the simplest species of figure, for can be produced by two heddles. It supposes no diff ence in the yarns as compared with plain weaving; it requ es no difference in the operations of the weaver; it requ es no increase in the number of the heddles; all it requ es is a different arrangement of the warps through the loop or eyes of the heddles, and when that is done, all the pro sses proceed as before.

Fig. 5.



I the above description we have supposed no difference in the colour of the warp and weft, the only alteration in the appearance of the cloth being produced by the threads of weft exposed on the surface of the warp; but it must be evident, that if the warp yarns consist of different colours, the cloth produced by the loom, arranged in the ordinary way, will be striped in the longitudinal direction of the web; and if the heddles be arranged as just described, the result will be a checked fabric, and this still without any change in the process of weaving.

The simplest variation in the operation of weaving, is the employment of two or more shuttles containing bobbins of different coloured threads. If woven in the common loom, the weaver making an equal number of shoots of two colours alternately, the cloth produced would be striped in the transverse direction. With the heddles arranged as above described, or with two coloured warps, any variety of check may be produced.

For the convenience of using two or more shuttles containing weft different in colour, fineness, or material, moveable shuttle-boxes are employed, so contrived as to slide up and down the swords or bars of the batten or lay, and by means of a loom capable of being adjusted to the shuttle-race on a level with the opposite driver.

A further means of varying the pattern consists in increasing the number of the heddles, each having a certain proportion of the warp-yarns attached to it, and each being moved by a separate treadle. The threads raised cover that shoot of weft which passes over the warp yarns not raised, and is exposed to view on their surface. The number of threads thus raised being capable of being varied as many times as there are heddles, being indeed capable of an immense number of combinations, it follows that figures may be described, or names and sentences woven in, to suit the fancy of the weaver, or the caprice of his customers. It will be observed that the employment of an additional number of heddles is only a contrivance to increase the weaver's means of varying the distribution of the warp, and consequently of the weft, for the one cannot be accomplished without the other; and when we add to this the employment of two or more coloured warp yarns, and of two or more coloured wefts, together with the adaptation of the said colours to the figure produced by the arrangement of the heddles, we at once perceive that the possible combinations are extremely numerous.

Twilled fabrics are extremely various and complicated in their character, and it is difficult to convey an idea of their structure within the space to which we are limited. The best way to gain a clear conception of the nature of a twilled cloth, is to take a small piece, say of merino or shalloon, and partially unravelling it, so as not wholly to disengage the weft from the warp, examine its structure through a single magnifier. It will then be seen that the weft yarns, instead of interlacing the warp yarns alternately and at regular intervals, as in the above figures, take up only every third thread, and that too at irregular intervals, so that the interlacing marches across the piece diagonally, and not transversely, thus:

Fig. 6.

In some of the finer fabrics, the interlacings occur only at the fourth, fifth, or sixth threads; and it is stated in the treatise on the silk manufacture, forming part of the Cabinet Cyclopædia, "that in proportion as the materials wrought are finer, longer intervals are allowed, until, in some of the finest silks, the interlacing takes place with only each sixteenth thread." P. 237. To aid the reader still further in gaining a clear conception of the nature of a twilled cloth, we subjoin a section (all the above being in the nature of *ground plans*, so to speak) cut across the piece, so as to expose the ends of the warp and the whole course of the weft. Here the shoot of weft passes over four yarns and under one. The next shoot will pass over the one and under the four. At the next stage of the process, the interlacing will shift one thread laterally, so as to produce the diagonal structure already described. We have already stated, that by increasing the number of colours, and varying the arrangement of the heddles, a considerable number of combinations may be produced. That number may, of course, be increased by an increased number of heddles; and the only check to this is the want of force possessed by a single weaver to work a large number, and the inconvenient manner in which they would crowd the space of an ordinary loom. To remedy these inconveniences, the draw-loom was formerly very generally resorted to, and it is now used to a very considerable extent in weaving carpets and figured damasks.

---

[1] On one occasion," says the Assistant Commissioner, "I saw a piece of shalloons woven under the following circumstances: 1. The man was the loom weaving; 2. a boy of ten years of age was winding bobbins; 3. the wife was at her husband's elbow picking the work; 4. his daug er was at the back of the loom taking off the broken threads of the warp. When the piece was taken home, the wages would be paid as th earnings of *one man*, yet the piece was really the work of a family." (Assistant Commissioners' Hand-Loom Reports, 1839, p. 599.)

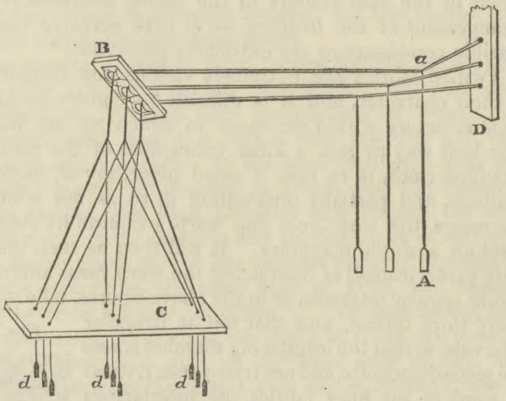
[2] has been computed that there are about 85,000 power-looms and about 250,000 hand-looms in Great Britain.

Fig. 7.

A reference to the article on Carpet-Weaving, and to the plates belonging to it, will explain the general nature of the draw-loom; but the harness part requires further explanation. The harness of the draw-loom is so arranged that no part of the warp is depressed, but such of the threads as are to be above the weft are raised, and the shuttle is passed through.[1]

Each cord of the harness of the draw-loom has a metallic eye or loop for the warp, called a *snail*, and the cord is kept stretched by a weight of lead. A frame C is placed horizontally over the loom, either perforated with holes or divided by wires, so as to form guide-holes or guide-pins to the cords of the harness. In practice the cords are very numerous and close to each other, as in the plates already referred to; but their operation will be best understood by exposing a small number, as in the annexed figure, which may be deemed an analysis of the gearing of the draw-loom.

Fig. 8.



The perpendicular cords A, called the *simples*, and terminating each in a handle called a *bob*, descend from the *tail* of the cords, each of which passes over a pulley at B, and is made fast to a piece of wood at D, called the table. If one of the handles or bobs A be pulled, it will depress the tail of one set of cords at *a*, and raise the set or system of cords *d d d* attached to it. In addition to this harness, the loom is geared in the ordinary way with heddles and their corresponding treadles, so that the weaver works as usual; and all that the draw-loom does, is to raise a portion of the warp out of the weaver's way, and so marking a certain portion of the figure, so long as the portion of the warp included in each set of cords affected is kept above the weft. When the figure requires a change, the cord previously held down is permitted to regain its position, which it does by the combined operation of the warp yarns, and of the weights *d d d* attached to the cords. Another set of threads is then raised, and the weaver again works in the ordinary way as long as necessary.

But the draw-loom has of late years been to a considerable extent superseded by the *Jacquard* engine, so named from its inventor, a weaver of Lyon. It is not too much to say, that this machine, simple in fact, though complicated in its appearance, has raised the silk manufactures of Spitalfields to their present state of excellence. Until the introduction of this machine, the production of the superior figured silks depended wholly on the skill of the weaver, and that to a degree which few attained. The necessity of extreme carefulness and skill is now considerably diminished; in other words, the production of the most costly fabrics is laid open to a larger number of operatives.

The Jacquard engine may be attached to almost any loom, and is generally owned by the manufacturer, and is furnished to the weaver with the warp. It is fixed to the top of the loom, in a direction perpendicular to the harness, the cords of which are attached to the lifting hooks *a a a a*. Every one of these lifting hooks is passed perpendicularly through an eye in a corresponding needle *b b b b*. These needles lie in rows in the frame *c c c c*. Let it be remembered that the figure is a mere skeleton of the engine itself, as the holes and needles are extremely numerous, say eight rows of fifty each, forming as many leases in the warp. The horizontal needles protrude through the frame *c c* at *b b b b*, and are kept extended in their position by spiral springs *e e e*, placed in cavities at the opposite end of the frame *c c*. By this arrangement the needles have a play in the direction of the spring. They yield to pressure, and on its removal return to their former position. The needles have an elongated loop at the extremity nearest the spiral spring *f f*, with a pin passing through it so as further to limit the range of the needle. The following figure represents one of these needles, with its eye-let, loop and pin, and spring.

Fig. 9.

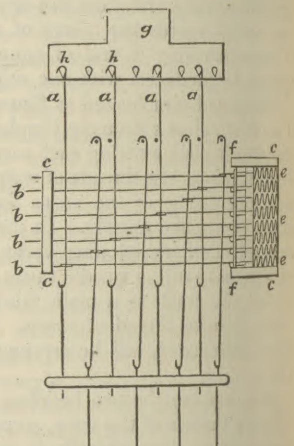


Fig. 10.

Immediately over the frame *c c*, is a corresponding frame *g*, having bars arranged across, that is, at right angles with the needles. There is one bar for every row of lifting hooks. This frame, when the engine is in operation, is alternately lowered upon the frame *c c*, and raised from it by a strong lever attached to the treadle and moved thereby. When the frame is lowered, the lifting bars, the ends of which are seen at *h h*, make their way immediately under the curved ends of the lifting hooks, so as to raise them, or such of them as are not prevented from being taken up, in the manner presently to be described, when the frame is raised. Supposing all the wires to be taken up, the hooks will appear as at fig. 13; but that would take up the whole warp.

---

[1] Carpet-weaving is the only branch of manufacture in which we have seen the *picker* or fly-shuttle dispensed with. In Mr Howard's carpet factory at Leeds, where many colours are used in the warps, the shuttles are thrown in the primitive manner.

It should be observed, that the lifting bars are shaped like blunted knife-blades, having the broad part inclined out of the perpendicular, so that in descending their lower edges steer clear of the curved head of the lifting hooks. As however they descend still farther, the flat parts of the bars press against the curved heads and force them against the springs. The lifting bars, still continuing to descend, at length get entirely below the curved head, when the spiral springs cause the horizontal needles, and consequently the lifting hooks, to regain their position; and when the frame *g*, with its lifting bars, is again raised, the bars must necessarily raise the lifting hooks.

In order to prevent the taking up of the whole warp, it will be obvious that any pressure upon any number of the horizontal needles at *b b* will force in the spiral springs, and thus remove the lifting hooks out of the reach of the lifting bars. In fig. 9, half of the hooks are so pressed in. To produce a figure, therefore, all that is necessary is to have the power of regulating the order in which the needles *b b b b* are pressed forward upon the spiral springs; and this is effected by means of a square revolving bar, fig. 11, pierced with holes corresponding in number and position with the needle points *b b;* and a number of perforated card-boards, fig. 12, which pass over it in endless succession with its revolutions.

Fig. 11.

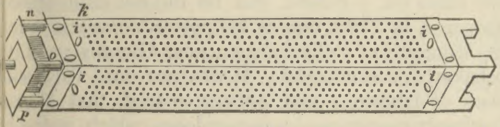

Fig. 12.

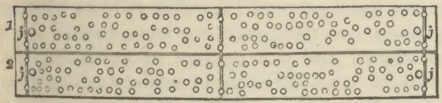
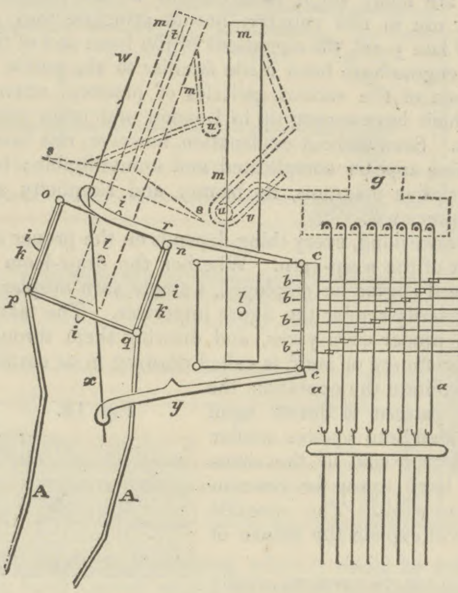


The reader will now clearly comprehend the operation of the bar and the cards. If the bar be moved against the frame *c c*, the needle-ends *b b* will pass into the holes, and all the lifting hooks will remain within the influence of the lifting bars; but if the cards, fig. 12, being partly perforated and partly whole, be placed over the perforated bar, it must be obvious that such of the needles as are prevented from entering the holes of the bar, by the intervention of the unperforated portions of the cards, will be pressed against the springs, and the lifting hooks will be removed from the operation of the lifting bars; while those needles which pass through the perforated portions of the cards into the corresponding holes of the bar will be unaffected, and the lifting hooks connected with them will be taken up.

As the perforation of the cards is the means by which the harness is raised, the absence of perforation determining what part of the warp shall not be raised, it is necessary to have one card or slip for every shoot of weft, until the whole pattern is described. The whole are loosely looped together at the corners, so as to form an endless chain, one whole revolution of which completes the pattern.

The cards are exactly fitted to the bar by means of studs *i i i i* upon the latter, corresponding with larger perforations *j j j j* in the former. The studs will be seen projecting from the section of the bar in fig. 13, the lettering of the whole of which figure corresponds with the others, so as to enable the reader to trace each part of the machine.

Fig. 13.



The mode of setting the Jacquard engine in operation is as follows: The bar, fig. 11, marked *k* in the section, the end only being there seen, is suspended in a frame *m m* by its axis *l*, which is swung so as to hang something like the lay or batten of the loom, and to move upon the side of the frame *c*, through which the needle-ends protrude, and to retire therefrom with an equable motion. It will be seen by fig. 11, that the bar has at one end four pillars *n, o, p, q; n, o,* and *p* only being seen in fig. 11. Each of these pillars is seized in succession by the hook *r*, by which means each revolution is divided into fourths. The equability and precision of this movement is secured by the T-shaped bar, which is pressed uniformly on the uppermost pillars by the action of a spring.

A careful inspection of figs. 9 and 13 will now, we hope, convey to the reader a clear conception of the manner in which the machine works. It will be seen that a roller *u* is attached to the frame *g* by a curved arm. This roller works in a hook-shaped bar *v*, and as the frame *g* is raised, the roller *u* ascends with it, and necessarily moves the frame *m*, to which it is attached, away from the frame *c*, through which the needle-heads project. In like manner, when the frame *g* is lowered, the roller *u* descending with it, the frame *m*, with the bar *k*, is permitted to approach the needle-heads *b b*. The section, fig. 13, shows the frame and bar in both positions.

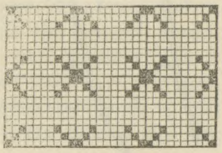
The revolution of the perforated bar is provided for by the operation of the catching hook *r;* for when the bar is in its place against the needle-heads, the hook slips over the furthermost pillar, and there the bar would be firmly locked against the frame *c*, if it did not revolve on its axis; and it can only yield to the repelling operation of the roller *u*, by making a quarter revolution. It will be readily seen, that the revolution is the only means by which the pillar of the bar is extricated from the hook.

The use of the under hook *y* is to reverse the operation. The hooks *r* and *y* are connected by a cord *w x*, by which the former is thrown out of action, and the latter brought into operation. The movement of the card-slips is of course reversed; and the weaver is enabled to repair an accident, such as the breaking of a warp-yarn, so as to avoid any break in the pattern. The lines marked A, A represent the chain of perforated cards.

There are many slight modifications of the Jacquard engine in use in this country, but in principle they all agree. Of late years, the operations of the loom and of the Jacquard engine have been made familiar to the public in consequence of the various galleries of practical science and art which have sprung up in London and other cities and towns. Seen without explanation, however, this beautiful machine appears complicated and unintelligible; but with descriptive diagrams, its beauty and simplicity are readily appreciated.

In figure-weaving, every thing depends on the proper arrangement of the warp-yarn. Whether the draw-loom or the Jacquard engine be employed, a single yarn misplaced must necessarily render the figure imperfect. The taking up of the proper warp-yarns, and drawing them through the appropriate *eye* or *mail*, is called drawing in or cording in. To facilitate the operation, the design or pattern is drawn upon paper, divided into squares similar to the patterns sold in the shops in all our large towns for German embroidery work. The annexed diagram will explain the nature of the design.

Fig. 14.



In cording in, two persons usually work together, one taking up the threads, and the other counting off the pattern. Thus, in the annexed figure, the direction given to the first arrangement of the warp-yarns could be, "Take up one"—"pass eight"—"take up two"—"pass eight"—"take up two"—"pass eight"—"take up one." In this way he proceeds from shoot to shoot, until the draught is completed. It will be observed that the counting is facilitated by every ten spaces being divided by stronger lines.

To punch the holes in the cards for the Jacquard engine, an ingenious machine is employed. It is a sort of counterpart of the engine itself, being provided with lifting cords, wires, and needles, so arranged, that by pulling the cords, the needle-heads are protruded. Answering to the revolving bar, and in front of the needle-heads, is a perforated iron plate, about two inches thick, provided with a set of moveable punches, which are driven forward by the protrusion of the needle-heads, and deposited in another perforated plate temporarily placed to receive them.

In order to move the proper cords, and so deposit the proper punches destined to describe the pattern on the card, the operation of drawing in is performed on a frame provided with a number of vertical threads answering to the warp of the goods to be woven. These threads are taken up with a long needle by one man, another directing as before; and when completed, the proper threads are attached to the corresponding cords of the punching machine, and the proper punches are deposited in the moveable plate. This being done, the blank card is placed against the face of the moveable plate, and against the cutting end of the punches. Both are then removed together, and placed upon another perforated plate, when the punches are driven through, and the card is cut at the requisite spot. Each card is numbered, so that there cannot be any mistake in attaching them together; and as every part of the punching machine gauges with the corresponding part of the Jacquard engine, the precision throughout is perfect. Our space will not enable us to be more explicit, but we apprehend the ample explanations we have given of the Jacquard engine will render the operation of punching the cards intelligible.

We have already described the perfection which the art of automatic spinning has attained in this country; but it must be obvious, that without the substitution of mechanical for manual power, these great inventions would have been comparatively inoperative. The idea of applying mechanical power to weaving was promulgated by M. de Gennes, and is mentioned in the Philosophical Transactions as early as 1768. In 1787, a rude loom, moved by mechanical power, was constructed by the Rev. Dr Cartwright, who took out a patent for it in August of that year. The idea first obtained possession of his mind by conversing with some gentlemen of Manchester, when it was observed, that on the expiration of Arkwright's patent, so many spinning-mills would be created, that a sufficient number of weavers would not be found to weave the yarn produced.[1] "Then," said Dr Cartwright, "Arkwright must set his wits to work to invent a weaving-mill." This was pronounced impracticable; but on his return home, Dr Cartwright exerted his ingenuity, and produced his machine in 1787. He was not sufficiently acquainted with the principles of mechanics; and after spending about L.40,000 in a factory at Doncaster, he was compelled to abandon his design.

In 1789, two years after the completion of Dr Cartwright's machine, Mr Austen entered a caveat at the patent office for a patent, but he did not then prosecute it. However, in 1798, one of his power-looms was erected by Mr Monteith of Pollockshaws, near Glasgow; and it seems to have been successful. It was not until 1813, after ten years of laborious and expensive trial, that Horrocks of Stockport constructed a power-loom, which is the basis of Messrs Sharp and Roberts's power-loom, the compact and efficient machine now in use.

From the description of the ordinary loom which we have already given, and from what we have said of the motions to be produced and the method of producing them, the reader will have no difficulty in understanding the following diagram (fig. 15), exhibiting the front view of a power cloth-loom, such as is now used in the principal factories of Leeds.

The frame-work A A A A is of cast iron, and is made of great strength, so as to support the heavy work which the cloth-loom has to undergo.

B is the breast-beam, against which the weaver stands, and over which the woven cloth passes in its way to the cloth-beam C, around which it is wound as the work proceeds. The breast-beam is made smooth, the edges being rounded, so that the cloth meets with no impediment in its progress round the cloth-beam.

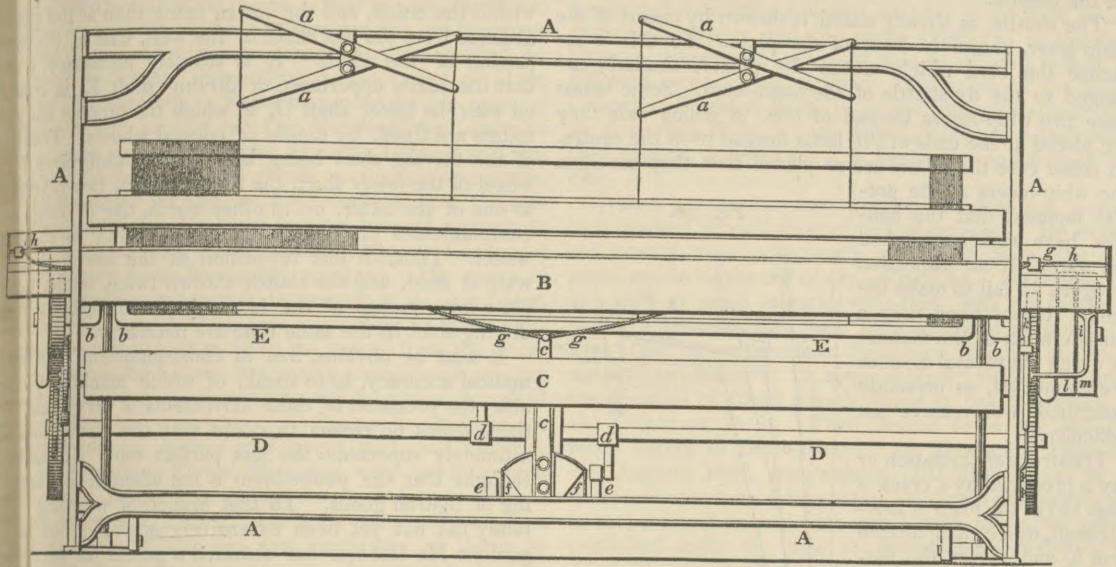
At the back of the loom is a corresponding arrangement for the warp; that is, there is a warp-beam parallel with the breast-beam, and a roller parallel with the cloth-beam, so that the plane of the warp is kept in a horizontal position. Its tension is preserved by a weight slung round the warp-roller, and acting in a direction contrary to the winding of cloth-beam. The manner in which this operates will be seen by inspecting figure 16.

The mode of suspending the heddles is shewn by the let-

---

[1] This was afterwards the case, as indicated by the advance which took place in weavers' wages. In the Report of the Assistant Hand-Loom Commissioners, already quoted, we find a weaver, named John Milner, stating his earnings as follows: 1800, 10s. 1804, 17s.; 1814, 34s. 6d.; 1815, 31s. 6d. After this, the number of weavers increased rapidly. Men from the plough learned to weave; children were taught in great numbers; and by 1830, the wages of John Milner had declined to 21s.; in 1831 they were 18s.; in 1835, 15s. 6d.; and in 1838, 12s. 6d. The high wages of 1814 were clearly the effect of the improvements in spinning; and it is well known in the manufacturing districts, that the master-manufacturers had to seek weavers in all directions.

Fig. 15.



ers *aaa*. In the smaller looms, used for cotton or worsted weaving, a single cord passing over a roller is found to be sufficient; but in weaving broad cloths, which are set in the loom twelve quarters in width, to allow for shrinking in the fulling and scouring, the length and weight of the gearing requires double support.

The cranks, by which the lay or batten is put in motion, as shewn in figure 18, are marked *bbbb*. The reader will observe that it is only their lower portion that can be seen, the upper part being concealed by the breast-beam.

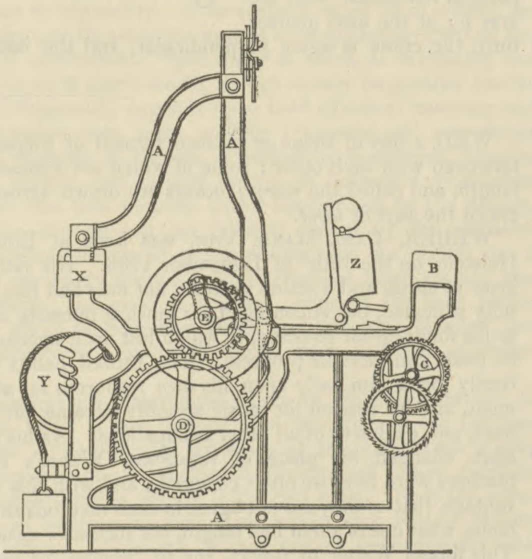
The shuttle in the loom here represented is thrown by a single whip-lever in the centre of the loom, moving alternately to the right and left, instead of by two levers, one placed at each end of the loom. The sudden jerk necessary for the sharp motion of this picking lever, which, be it observed, must imitate the sharp motion of the weaver's right hand, is produced by the rollers *d d* affixed to the shaft D, which, at every half turn of the said shaft, strike down the rollers *e e* alternately, and draw the whip-lever *c* towards them by shortening the cords *f f*. The picking cord *g* being thus alternately drawn to the right and the left, moves the shuttle along the shuttle-race *h h*, in a manner with which the reader must be familiar.

The mode of throwing the loom out of gear is that which must be familiar to every one who has seen machinery of any kind worked by a shaft and band. *l m* is a split drum, *l* being connected with the shaft, and *m* being unconnected therewith. It follows, that when the band is brought over the drum *l*, the shaft is necessarily set in motion, whereas the instant it is cast off upon the loose drum *m*, the machinery is stopped. The band is cast off and the loom thrown out of gear by means of the lever *k*, which, when pushed to the right, moves the forked lever which holds the band *i* in a lateral direction sufficiently to effect the purpose.

Figure 16 is an end view of the loom; X being the cloth-beam, Y the roller, and Z the batten, the motion of which is described by figure 18.

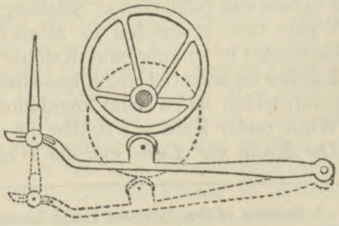
After the description already given of the motions necessary to the weaving of a piece of cloth, very little further explanation is necessary to enable the reader to understand the operations of the power-loom, and the manner in which motion is communicated, from its first source, to the heddles, the shuttle, the batten, and the warp, all of which correspond with unerring regularity; conducting the work with a degree of precision which it would be wrong to say the hand cannot attain, but which certainly can only be achieved by the skilful few.

Fig. 16.



The motion of the heddles is produced by two eccentric wheels or tappets, acting upon two levers or treadles, furnished with friction-rollers. While the short radius of one tappet is on one treadle, so as to permit the elevation of the corresponding heddle, the long radius of the other presses down the other treadle. Fig. 17 exhibits one of the tappet-wheels, the short radius pressing upon its treadle, the dotted lines showing its position on its

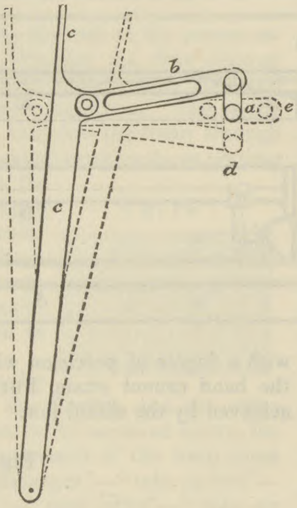
Fig. 17.



half revolution, when the long radius is brought to operate on the treadle.

The shuttle, as already stated, is thrown by means of the whip-lever, shown in front of the plate. To this is attached the cord which moves the picker, similarly arranged to the fly-shuttle of the hand-loom. Some looms have two whip-levers instead of one, in which case they are placed at the ends of the loom instead of in the centre. In either case the rollers are so placed that they act upon the whip-levers at the precise moment that the heddles have sufficiently shed the warp. If an inspection of figure 15 fail to make the reader comprehend this, a consideration of the manner in which the several motions are connected, as presently described, will remove the difficulty.

Fig. 18.



The stroke of the batten or lay is produced by a crank *a* (fig. 18) in the main or driving shaft, which elongates the arm *b*, and moves the batten *c c* forward against the last shoot of the weft. The dotted lines show its alterations of position. At the first quarter turn of the crank, it is brought to a position horizontal with the arm *b;* at the next quarter turn, the crank is again perpendicular, and the batten is in its middle position; at the third quarter turn, the crank is again horizontal with the arm, a portion of the arm being within the crank, and the batten being then at the greatest distance from the last shoot of the weft, that is, the woven portion of the cloth. It is scarcely necessary to add, that the main, uppermost, or driving shaft E, is connected with the lower shaft D, to which the tappets and jerk-rollers are fixed, by means of cogged wheels. The wheel of the driving shaft being half the circumference of the wheel of the lower shaft, the former makes two revolutions to one of the latter, or, in other words, the driving wheel communicates just half of its own velocity to the lower wheel. Thus, in one revolution of the lower shaft, the warp is shed, and the shuttle thrown twice, while, to complete two strokes of the batten, two revolutions of the driving shaft in the same time are necessary.

It must be obvious, that in consequence of the mathematical accuracy, so to speak, of which machinery is capable, the precision of these movements is very great; and there seems no reason to doubt that the power-loom will ultimately supersede the less perfect tool. It has been thought that the power-loom is not adapted to the weaving of figured goods. To that branch of weaving it certainly has not yet been extensively applied; but the ingenious Mr Roberts has obtained a patent for certain machinery to be placed over the loom, and calculated to produce effects similar to the Jacquard engine, and we have no doubt that in time all the difficulties will be overcome.

It must likewise be obvious, that unless the improvements in weaving correspond precisely with those which we have already described in the article SPINNING, some portion of the ingenuity expended in the latter branch of manufacture must be of no avail.[1] (D. L.)

WEB, a sort of tissue or texture formed of threads interwoven with each other; some of which are extended in length, and called the *warp;* others are drawn across, and called the *weft* or *woof.*

WEBER, CARL MARIA VON, was born at Eutin, in Holstein, on the 18th[2] of December 1786. His father, a lover of music and a skilful violinist, not only had him carefully educated, but encouraged his musical pursuits, as well as his fondness for painting, in which last art it appears that he made considerable progress. The retired habits of his family threw him early upon his own resources for amusement, and his passion for music speedily became predominant, and exclusive of all other occupations. As his father often changed his place of residence, Weber's music-teachers were likewise often changed; and with this disadvantage, that as they did not agree in their methods and opinions, what one of them had taught, his successor untaught. This forced Weber to reflect, and to become his own instructor. In 1796–7 he received valuable lessons in pianoforte playing from Hauschkel of Hildburghausen. He was next placed under the care of Michael Haydn at Salzburg for composition, but made little progress under that master, who was then very old. In 1798 his first work of six *Fughetti* was published at Salzburg, and was well received. Weber then proceeded to Munich, where Valesi became his master in singing, and Kalcher in composition. From Kalcher he acquired much knowledge of the art of counterpoint, which laid a solid foundation for his future studies. While under Kalcher's tuition, he composed his first opera, *Die Macht der Liebe und des Weins* (the Power of Love and Wine); besides a mass, sonatas, and variations for the pianoforte, violin trios, songs, &c. all of which he afterwards destroyed. His next opera, *Das Waldmädchen* (the Wood Girl), was performed in November 1800, and met with more success at Vienna and St Petersburg than he himself was pleased with afterwards, when his judgment had become more matured. In 1801 he composed at Salzburg his opera, *Peter Schmoll und seine Nachbarn* (Peter Schmoll and his Neighbours), which was performed at Augsburg, but with indifferent success. In 1802 he went on a musical tour with his father to Leipzig, Hamburg, and Holstein, and during this time studied a number of theoretical works, from which, it seems, he derived little benefit. Dissatisfied with these, he endeavoured to form a system of his own, and to apply it to an analysis of the works of the old composers. In this he succeeded to his own satisfaction. The next important step in his career was his visit to Vienna, where he became acquainted with several eminent musicians, among others Haydn and Vogler, under the latter of whom he studied hard for about two years, enriching his mind and developing his powers by a close examination of various masterpieces of composition. Meyerbeer, Gänsbacher, and G. Weber, were at this time his fellow-pupils under Vogler. During these studies he only published some variations and a pianoforte arrangement of Vogler's opera of *Samori.* Being called to Breslau as music-director, he availed himself of his new position to obtain a knowledge of choral and orchestral effects. At Breslau he composed the greater part of the opera of *Rübezahl* (Number Nip). In 1806 he was invited by Prince Eugene of Würtemberg to his court at Carlsruhe in Silesia, and there composed two symphonies, some concertos, and other pieces. War having driven him from this asylum, he resolved to abandon his public career till more favoured by circumstances; and he resided for some time in private tranquillity in the house of Duke Louis of Würtemberg. There he composed his opera of *Silvana*, on the basis of his *Die Waldmädchen*, and also wrote a piece named *Der erste Ton* (the First Tone), besides some overtures, choral pieces, and pianoforte works. In 1810 he again set out on a professional tour through Germany, and from this time devoted himself entirely to his art. At Frankfort, Munich, Berlin, Vienna, &c. he and his works were most favourably received. His opera of *Abu Hassan* was composed at Darmstadt in the same year. Between 1813 and 1816, he was opera-director at Prague; but giving up that post in 1816, he ceased from his musical occupations for a time, contenting himself with visiting various places, and quietly waiting till he should be called to new and greater exertions. At Prague he produced his celebrated cantata, *Kampf und Sieg* (Battle and Victory). He declined various liberal offers that were made to him, until he was induced to accept an invitation to form a German opera at Dresden. There he composed his opera, *Der Freyschütz*, which was first performed at Berlin in 1821 with extraordinary applause. At Dresden he produced in 1822 a drama called *Preciosa*, which was most favourably received. His opera of *Euryanthe* was also composed at Dresden, but first brought out under his direction at Vienna in 1823, where, as he himself says, "it was received with indescribable enthusiasm." At Berlin his Euryanthe was rather coldly received, and was there nicknamed by some musical critics *L'Ennuyante.* It has been said that the *Libretto* of this opera was so confused and ill-constructed, as to overpower the beauty of the music. A three-act comic opera, *Die drei Pinto* (the Three Pintos), which Weber had begun at Dresden, remained unfinished, and was bequeathed by its author to his friend Meyerbeer, with a request that he would complete it. In 1822 Weber suffered from pulmonary illness, and still more severely in 1825. He appears, from some expressions in his letters, to have anticipated a premature death; and, unhappily, his prognostics were too speedily verified. In 1824 he began his opera of *Oberon* for London, which he appears to have finished about the end of 1825 or the beginning of 1826. At the end of February 1826 he set out for London, where he made his first appearance on the 8th of March at Covent Garden, as conductor of a selection from *Der Freyschütz*, and was received in the most enthusiastic manner. At this time his countenance betrayed the deep impress of mortal disease. On the 12th of April 1826 his opera of *Oberon, or the Elf-king's Oath* was performed at Covent Garden Theatre, and conducted by Weber himself, who was again greeted with the strongest testimonies of public favour. We now approach the melancholy close of this eminent artist's career. On the 26th May his benefit concert took place in the Argyll Rooms, but was very thinly attended. On this occasion, bodily illness and mental vexation so affected him that he was barely able to go through his duties as conductor. After the performance he sunk upon a sofa in an alarming state of exhaustion. Ten days afterwards, at seven o'clock in the morning of the 5th of June, he was found dead in his bed at Sir George Smart's house, where he had resided from the time of his arrival in London. On opening the body the same afternoon, the three physicians and the surgeon in attendance found the larynx and the lungs so diseased as sufficiently to indicate the cause of his death. Weber left a widow and two children. Unhappily he had no relative near him to close his eyes. His remains were interred in the vaults of the Catholic chapel, Moorfields.

---

[1] Reports of the Assistant Hand-Loom Commissioners. Essays on the Art of Weaving, by Duncan, 1808. The Cotton Manufacture of Great Britain, by Dr Andrew Ure. The Repertory of Arts and Manufactures.

[2] According to Weber's own account, he was born on the 18th; according to another account, on the 16th of December.

While writing this article, we observe that the Oldenburg government has ordered a bronze statue of Weber to be erected in Eutin; and also, that his works shall be engraved on copper, and the plates preserved in the ducal library. Impressions are to be sent as presents only to the different sovereigns of Europe. The artists of the King's Chapel at Dresden have, it is said, raised a subscription for removing Weber's body from London, to a tomb which they propose to erect for it in the public cemetery of that city.

Weber was an excellent pianist, but does not seem to have pushed himself forward in that capacity. He expressed himself most vehemently against all those who composed music by the aid of any instrument. He is described as a man of small stature, very thin, with an intelligent countenance; sensible, well informed, and very unobtrusive. His temper seems to have been amiable, and we do not find any traces of its being seriously ruffled, except on the occasion of Castil Blaze's piracy of the *Freyschütz* for the Odéon at Paris. Then indeed he wrote two very sharp letters to Blaze, dated 15th December 1825, and 4th January 1826, but without obtaining answer or redress. A number of interesting particulars regarding him is to be found in some his own letters and other papers, published under the title of *Hinterlassene Schriften von Carl Maria von Weber* (Posthumous Writings of C. M. von Weber), in 2 vols. 8vo, 1828. Among these are, his Autobiography, and "The Life of a Composer."

We have already mentioned his principal works, and their very favourable reception. It has been said that, in his Freyschütz and other operas, he borrowed largely from old popular German airs, and that he has no great claims to originality. If he adopted much from others, the children of his adoption were at least splendidly clothed and richly entertained. Still there is much of originality and beauty in Weber's works, though it may be granted that he more frequently depends upon bold effects of harmony and modulation than upon melodic invention and expression. The example of Mozart, extended by Beethoven, Rossini, and Weber, led to that system of unlimited modulation which has now become more familiarized to the musical public, though not yet relished except by the initiated. The whole history of music shows that the public ear is only gradually trained to innovations in harmony and modulation; and even at this day, some of the most elaborate works of Sebastian Bach, and his son Emanuel, are *caviare* to the multitude, from their extreme abstruseness.

Beethoven's magnificent opera of Fidelio, produced in 1805, gave a new impulse and direction to the German opera. The powerful influence of this great work is very perceptible in the operas of Weber and other German composers within the last thirty-five years. So is the influence of Beethoven's pianoforte music upon that of Weber and others. Although Weber cannot be compared with Beethoven for original and powerful genius, fertility and sublimity of invention, still he must be considered as a great master, possessed of much dramatic talent, great knowledge of his art and of orchestral effect, and a high degree of brilliancy and gracefulness in composition. His faults are, occasional dry and harsh construction, want of unity in melody and of determinate rhythm, and the occurrence of what are technically termed *strangled modulations.* Indeed, violent contrasts in harmony and modulation; fragmentary snatches of melody, often hard and dry, without leading and sustained subjects; the abuse of chromatic passages; vague and disjointed rhythm; are the faulty characteristics of too many composers of the modern German school when carrying license to extremes. This style may be called the transcendental dithyrambic of music; wild, disorderly, heterogeneous, anti-rhythmical. Weber however redeems his occasional faults by a profusion of beauties. His printed works are numerous. Besides the operas mentioned above, they consist of concertos, concertinos, pots-pourris, for the pianoforte, the clarinet, the oboe, the bassoon, and the violoncello; sonatas, variations, polonaises, &c.; symphonies and overtures, among which last the overture *Der Beherrscher der Geister* (the Ruler of the Spirits) is remarkably characteristic of Weber's peculiar style. Many of his songs published in collections are trifling; but his four-part songs, with pianoforte accompaniment, named *Leyer und Schwerdt* (Lyre and Sword), words by Körner, are excellent. A posthumous work of Weber's, a Stabat Mater for two soprano voices and one alto, was in 1826 intrusted by his widow to the music-director Rungenhagen of Berlin for publication. In his autobiography, he says that the following words may with justice be inscribed upon his tombstone: "Here lies one who meant honestly, and wished to act uprightly, both towards his art and towards his fellow-men." (G. F. G.)

WEBSTER, Alexander, D. D. was the son of James Webster, minister of the Tolbooth Church in Edinburgh, and was born in that city about the year 1707. He was only thirteen years of age at the death of his father, and of course could derive little from parental instruction or example. He studied, at the university of Edinburgh, the several branches of learning with great approbation, particularly those connected with the mathematics, for which he discovered an early predilection. He afterwards attended the lectures of the professor of divinity; and in the year 1733 he was ordained minister of the parish of Culross, and in June 1737 he was admitted as one of the ministers of the Tolbooth Church of Edinburgh. His eloquence was noble and manly, his piety conspicuous, and the discharge of his pastoral duties faithful and laborious. To these qualities he added an enlightened zeal for the external interests of the church, a jealousy of corruption, a hatred of false politics and tyrannical measures, which sometimes exposed him to calumny from the guilty, but secured him the esteem of all who could value independence of soul and integrity of heart.

The prosperity of fortune which placed Mr Webster in the church of his father, and restored him to the polished society of his native city, was not confined to these favours. Eleven days after his settlement in Edinburgh, he obtained the hand of Mary Erskine, a young lady of considerable fortune, and nearly related to the noble family of Dundonald. The genius of Mr Webster now began to unfold itself. Family connections extended his acquaintance with the nobility. Edinburgh then possessed a number of men, both in civil and ecclesiastical stations, who have saved or adorned their country. With these he was soon to cooperate in defending the Protestant interests from the arms and artifices of rebellion.

In the year 1733, five or six ministers seceded from the church; and being anxious to draw away as many as possible from the communion which they had renounced, they invited down to Scotland, in 1741, George Whitefield, a young preacher of great piety and extraordinary pulpit talents. On his way to Dunfermline, he was met and entertained at Edinburgh by Mr Webster and some of his brethren. From them he learned the state of church-parties in Scotland; and though he kept his promise of preaching first in Fife, he declined connecting himself with any particular sect. Disappointed of his influence and assistance, the Seceders ascribed the effects of his preaching to sorcery and the devil, while Webster, in a pamphlet which he published on the occasion, attributed them to the influence of the Holy Spirit, an opinion regarded by the Seceders as unspeakable wickedness.

In the year 1745, Webster remained in the city when it was taken by the rebels, and employed his universal popularity and vigorous eloquence in retaining the minds of the people in the interests of the house of Hanover. His exertions in this were not overlooked by most of the spirited gentlemen who acted in quelling the rebellion. He became an intimate friend of Duncan Forbes of Culloden, Lord Milton, and others. He preserved to the latest period of his career that activity both of mind and body which distinguished him in the prime of life, obtaining at last his frequent wish and prayer, an easy and peaceful death, after a very short indisposition, on the 25th of January 1784.

Dr Webster's character as a minister was popular in the extreme. To the poor he was a father and a friend, a liberal patron to poor students. In his person he was tall, and of a thin and meagre habit. His features were strongly marked, and the conformity of the whole indicated genius and independence. To him the widows of the clergy are indebted for the establishment of the celebrated scheme, securing them in an annuity proportioned to certain rates of payment; the plan of which he matured in his own mind soon after he was appointed a minister of the Tolbooth Church. The success of the scheme has been complete.

WEDGE, one of the mechanical powers. See Mechanics.

Wedge *Island*, on the south coast of New Holland, at the mouth of Spencer's Gulf, the largest of the group called by Captain Flinders Gambier's Isles. Long. 136. 29. E. Lat. 35. 11. S.

WEDMORE, a town and parish of the county of Somerset, in the hundred of Bempstone, 126 miles from London and five from Axbridge. It had formerly a market, which has of late years ceased to be attended. The population of the parish amounted in 1821 to 3097, and in 1831 to 3557.

WEDNESBURY, a town of the county of Stafford, in the hundred of Offlow, 124 miles from London and seven from Birmingham. It is a place of black and gloomy appearance, inhabited chiefly by persons employed in the extensive and valuable coal-mines in its vicinity, or in some branches of the iron manufacture. The parish church is a fine ancient Gothic structure. A new church has been built of late years, and there are many chapels for several sects of dissenters. The town has a good market on Wednesday. The population amounted in 1821 to 6471, and in 1831 to 8437.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named *Woden*, supposed to be Mars, worshipped on this day.

Ash-Wednesday, the first day of Lent, so called from the custom observed in the ancient Christian church, of penitents expressing their humiliation at this time by appearing in sackcloth and ashes.

WEEK, in chronology, a division of time comprising seven days. See Chronology.

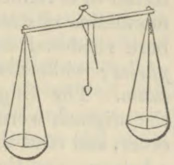
Passion-Week, or the *Holy Week*, is the last week in Lent.

WEERE, a small district of Hindustan, province of Cashmere, extending along the south side of the Jhylum, here about eighty yards across.

WEIGHING MACHINES. In this our concluding article on weighing instruments, we intend to supply such particulars as have not already been treated of under the heads of Balance and Mechanics. In doing so, we propose, in the first instance, to sketch shortly, and possibly with some novelty, the early history of the invention, which claims attention from the high antiquity it holds among the mechanical arts; and then to furnish descriptive notices of several balances, some of them of recent date, and not described, it is believed, or at least collectively so, in any previous work.

he most ancient instrument used for ascertaining weight, an the one from which the others were derived, was probabl the common or equal-armed balance. It may have been in nted much about the same period as the yoke or swingtr employed to attach two beasts of burden to a common lo . Both inventions were nearly allied in construction; an their approximation in the nature of the object to be ef cted by their instrumentality, leaves little doubt that th one originated the idea of the other. In their first rude fo mation, they seem to have been indiscriminately used, bo for weighing and equably dividing the labour of draft. A ordingly, the Greek words ζυγὸς and ζυγὸν, and their La n derivative *jugum*, were employed to signify either th balance or yoke. In the Hebrew, the word used in th oldest books of Scripture to denote the balance, is one wh ch is descriptive of the instrument itself, by having refe nce, through related words, to weighing and the ascerta ment of weight; while the word for yoke, without havin descriptive reference to any instrument, signifies litera *upon;* seemingly in allusion to an already known co rivance being laid as a yoke, over or upon the necks of he two draft cattle; a custom which still prevails in th east, as it anciently did in all countries. From the an ogy furnished by the double application of the Greek an Latin terms, it may be concluded, that the beam of he balance was the instrument thus apparently referre to, and that it was therefore the earlier invention of th two.[1]

hat the balance was the first of strictly mechanical contr ances, is not perhaps improbable. Its great antiquity is at sted by its being the only machine commemorated among th twelve signs. The name bestowed by the Greeks and R mans on this girdle of constellations was ζωδιακὸς, zodi , a word having reference exclusively to living creatu s. The balance being an inanimate object, seems th efore to have been long rejected by them, and its pl e supplied by giving to *Scorpio* a double share of the h vens; the twelve names being then completed by appl ng the word *Chelæ*, to denote that half of the sign into w ch the two claws of the animal extended. The introdu tion of *Libra*, or the balance, does not seem to have be n fully sanctioned even in Virgil's time; for although el where named by him, he describes its place as offering a vourable vacancy for the reception of Cæsar among the co stellations; and poetically figures the scorpion's claws as lready contracting to make room for him.[2] The anci t claims of the balance were however revived, and the na e of *Chelæ* disappeared from the number of the signs. A ong other nations, the balance held its place in the zodi from the highest antiquity. Along with the other si s, it is sculptured on the most ancient monuments of E pt; but that this was not their birth-place, may be infe ed from the contrast between the figures of the signs an those native and strangely fantastical devices with which th Egyptian monuments are otherwise so profusely covered The Abbé Pluche, arguing from another circumstance, viz. the non-accordance of the seasons in Egypt with those which he considers the signs as marking, traces their invention to the plains of Shinar, and refers it to the near descendants of Noah.[3] The annexed figure represents an ancient and well-formed balance from Egyptian sculpture. For the sake of distinctness, however, it is here shown as off the equilibrium. A line and plummet hang from the beam, to mark when a tongue, which points downward, reaches the vertical position. Others, of a much ruder description, and without any contrivance to indicate equilibrium, are given by Rosellini, from ancient Egyptian paintings.



The steelyard has generally been regarded as of greater antiquity than the common balance; but in point of conception it is less simple, and likely therefore to have been of subsequent invention. The correctness of this inference admits perhaps of being fully established. In Job and the Pentateuch, by much the oldest records extant, the Hebrew term employed to denote the balance is *moznaim*, a word of plural, or, as pointed by the Masorites, dual import. The kind of balance intended by it can be no other therefore than the common one; the dual word *moznaim* evidently bearing reference to the two scales.[4] That it cannot mean the steelyard, appears to be clear, because in it only one scale was required, while in every respect it is destitute of any double member from which a dual name could have arisen. This view, which appears to be decisive, is confirmed by the definition given of the word by Gesenius, who explains it to mean *the balance, properly a pair of scales.*[5]

The common balance being therefore the one mentioned in Job, is ascertained to have been in use 2130 years B. C. or 218 years after the deluge.[6] How much earlier than this it may have been used, cannot safely be conjectured. The knowledge of it probably came down, through Noah's family, from antediluvian times; for without some means of ascertaining weight, the ordinary transactions of every-day traffic could not in any age have been carried on.

From the preceding observations, it appears likely that any allusion to the steelyard in the Bible should be made by a noun possessing a strictly singular termination. The earliest use of such a word having reference to the subject, is in the time of Solomon, about 1014 years B. C. It occurs in Proverbs, xvi. 11, where the term *pheles* (explained by Gesenius, p. 643, to be *a balance, equipoise, properly a steelyard*) is followed by the word *moznaim*, already noticed. In the English version, this passage is translated *a just weight*[7] *and balance*, &c. A more correct rendering would be, *a just balance and scales;* first, because *pheles* has been preserved in the Arabic to the present day as meaning, not a weight, but a weighing instrument; and, secondly, because the word occurs again in Scripture, viz. Isaiah, xl. 12, where its sense is fixed by the immediate

---

Archdeacon Woodhouse (on the Apocalypse, 1805, p. 144), in explaining some peculiar views in regard to the translation of the Greek we ζυγὸν, gives priority to the yoke, rather incidentally perhaps than otherwise, since the question of date does not affect his argument.

Georgics, i. 32.

Pluche, Histoire du Ciel, Paris, 1739, v. i. pp. 18–30. A short memoir of this author will be found in its proper place in a former volu of the present work.

In nine passages of our version of the Bible, *moznaim* is translated in the plural *balances*, and in seven passages *balance*. Were the term sc employed for the plural rendering, and *pair of scales* for the singular, the English would express the original with much fidelity.

Leo's Gesenius, Cambridge, 1825, p. 386. The argument (in support of which Gesenius is here quoted) receives similar confirmation fr the Greek, in which the singulars ζυγὸς and ζυγὸν were generally employed to denote the yoke, and their *plurals the balance.*

The chronology here followed is the common one, adopted and specially vindicated in this instance by Townsend (Chronological Arra ement of the Old Testament, 1826, v. i. p. 28). Dr Andrew, in his Scripture Chronology, 1822, p. 33, dates the time of Job 2215 years B. and Dr Hales, in his Analysis, vol. i. p. 185, 2337 B. C.

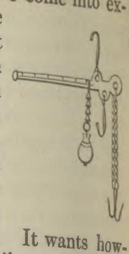
Among the Hebrews, as among the Greeks, the shekel, maneh, and talent, were names of particular weights, by which their money and ot precious articles were weighed. The Hebrew word for commercial or general weight was *eben*, literally *a stone*, and *ebenim*, in the pl l, *stones;* probably the origin of the term stoneweight.

Weighing Machines. context. In this passage, as in the former instance, the word *pheles* precedes *moznaim*, both words being brought together, and occurring in a parallelism. The passage referred to is rendered in our version, " who hath weighed the mountains in scales, and the hills in a balance." The word here rendered scales in the plural, is the singular noun *pheles;* while that rendered balance, is the dual word *moznaim.* The English therefore would better accord with the original, were the terms in the translation reversed in order, and read thus: " who hath weighed the mountains in a balance, and the hills in scales."

Whether *pheles*, however, means properly a steelyard, as Gesenius defines it, may be doubted. The reason for supposing it does, seems apparently to rest on the circumstance that *kapheles* in the Arabic (most probably a corruption of *hapheles*, the definite form of the Hebrew word) is the name of the Arabian weighing instrument of the present day; and because it now is a steelyard, and is known to have been in long and almost exclusive use in Arabia, and indeed in all Asia, that therefore the related or parent word *pheles* must denote the steelyard. But this rests on the assumption that the common balance had never been known to the Arabians. Job, however, who is shewn to have been an Idumæan Arab, and to have resided in the north of Arabia,[1] does not use *pheles*, but *moznaim*,[2] to express the balance; a word which, as already shewn, denotes the common or equal-armed one, and at that period of course undoubtedly used in Arabia.

Perhaps both words may therefore be regarded as synonymous terms for the common balance; the one descriptive of it by reference to its beam or balance-rod, and the other by reference to its pair of scales. This view receives further confirmation from the circumstance that there is one Hebrew word in the Bible which may be shewn to refer with some distinctness to the steelyard. Isaiah, in a passage subsequent to that above quoted, when describing the construction of idol images, says, " they (the Babylonians) weigh silver in the balance," &c. (chap. xlvi. 6); and here makes use of the Hebrew word *kaneh* to denote the kind of balance meant. Gesenius, p. 699, explains this word to be *a cane, or measuring reed, or scale for measure; a beam or lever of a balance, or balance itself.* The word has thus evident reference to a graduated staff or beam,[3] and probably therefore when used, as in the present instance, to express a weighing instrument, denotes rather the graduated steelyard, of which it is thus descriptive, than an ordinary balance or pair of scales. As it is not used to express a weighing instrument in any other passage of the Bible, and as Isaiah is here giving a minutely graphic picture of the process observed by the Babylonians in the manufacture and correct adjustment of the weight of their gods, it is probable that the instrument named was an eastern invention, constructed in all likelihood of the sugar or " sweet cane," a sense in which the word *kaneh* is also used.[4] These remarks appear to receive some illustration from the fact, that in China and the East Indies a small steelyard (described in our article Balance, p. 306) is employed to weigh precious metals, gems, &c.; and to this day is made of wood or ivory, and not improbably also of cane, a substance which, from its combined lightness and strength, is well suited for the purpose.

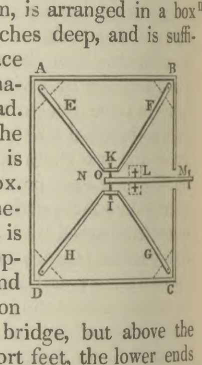
This is probably the first mention of the steelyard on record, viz. in Isaiah's time, or about 780 years B. C.; at which period it thus appears to have been in use among the Babylonians. It seems to have superseded the common balance in Asia; and, through the Romans, to have come into extensive use in Europe. The annexed figure is a representation of one made in the first century, and not long since recovered from the ruins of Pompeii, which town, with many of its inhabitants and their utensils, lay buried, for nearly eighteen centuries, in the shower of volcanic matter thrown out by Vesuvius, A. D. 79. Like some of our steelyards, this ancient one is provided with two different centres of suspension. It wants however the knife-edged bearers now universally used. In the progress of invention, the modifications of the steelyard have become numerous in the form of compound machines; but these are of comparatively modern date, and do not require successive detail. Descriptions of the most useful varieties of the balance will be found here, and under our previous articles on the subject; and as it is intended to embrace the present opportunity of classifying their different kinds under distinct heads, references to those already described will be introduced in their proper place.



I. *Balances acting as Levers round one or more Fulcra, and requiring experimental Adjustment when used to ascertain the Weight of a Substance.*

To this class belong the Common, the Roman, the Chinese or Indian, the Danish or Swedish, already described under Balance and Mechanics, pp. 358 and 370; and Magellan's, Mr Bate's, and Dr Black's, under Mechanics, pp. 371 and 456.

This is a compound steelyard, and is used for ascertaining the weight of loaded carts. The apparatus, of which a ground-plan is here given, is arranged in a box ABCD, which is about twelve inches deep, and is sufficiently sunk in the ground to place the highest part of the completed machine on a level with the line of road. A fixed wooden bridge, by which the horse may pass across the machine, is laid over the middle part of the box. At each side of this bridge is a metal wheel-track. On these the cart is rested by its two wheels and a prop-staff. The tracks are fixed to and borne up by a platform (or skeleton frame) placed below the wooden bridge, but above the works. The platform has four short feet, the lower ends of which are formed into small hemispherical cavities. These cavities rest at E, F, G, H, on pointed studs about an inch long. The two studs at E and F are fixed on the crooked lever AKB, with their points upward, and the two at G and H are similarly fixed on the companion-lever DIC. Sharpened studs, also about an inch long, project downward from the four extremities of the crooked levers. The points of these studs rest in small hemispherical cavities, formed at the upper ends of blocks which are fixed as bearers for them in each corner of the box. The short parts of the crooked levers parallel to OL, and near the middle of the box, have their under edges sharpened, and rest on the angle of a sustaining fulcrum IK, which passes through, and is fixed to the lever OM. This lever is also crossed at L by the fulcrum which forms the common centre of movement for the whole machine. The angle of the fulcrum points downward, and rests, as in the ordinary



---

[1] Horne's Critical Study of the Scriptures, 1825, v. iv. pp. 74, 75.

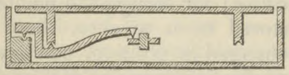
[2] Job, vi. 2, and xxxi. 6.

[3] In this sense it occurs in many passages. Thus, Ezekiel, xl. 3–5: " With a line of flax in his hand, and a measuring reed...and in the man's hand a measuring reed of six cubits long; so he measured the breadth of the building," &c.

[4] Thus, in Jeremiah, vi. 20: " To what purpose cometh there to me incense from Sheba, and *the sweet cane from a far country*; your burnt-offerings are not acceptable, nor your sacrifices *sweet* unto me."

bal ce, on concave arcs, situated one on each side of the leve OM. These arcs are formed on the upper end of a bloc, which rises from and is fixed to the bottom of the box The lever is again crossed at M, by a fulcrum having s angle pointing upward; and from this angle a receiving scale for the weights is hung by a shears or double ring In cases where it is wished that the machine when unl ded should preserve equilibrium, the lever OM is prolong d to the left, and loaded at that end, to the extent req site to balance the weight of the levers.

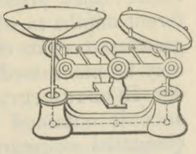
ide view of BK, one of the limbs of the crooked lever AK is here given, in the direction of the diagonal BD. Th lever, as shewn in the figure, is kneed to an extent suff ent to admit of the angul points of the fulcra being laced in the same horizon l line. The other limb AK s of the same shape. The form of the entire lever AK is thus easily understood. Its companion lever DIC is o the same construction. The limbs of the levers are the fore so shaped that the fourteen sharp bearing parts of a the fulcra are situated, during equilibrium, in one horiz tal plane. These bearing parts, and the parts they bea against, are all formed of polished steel.



I now EA be supposed a tenth part of the length of EK, the 100 pounds placed on the platform, or on the wheel-tra s, and pressing therefore on the studs E, F, G, H, wil e sustained by ten pounds of an upward pressure at IK And if, again, OL be a tenth part of LM, the ten pou ds of upward pressure will be given by one pound pla d in the receiving scale at M. These proportions are ass ed, for easy arithmetical illustration; but in the practic construction of the machine, the distance between the res g points at E, A, and at O, L, is made to bear a gre er ratio to the distance between the resting points at E, , and at L, M, than has here been supposed. Instead of ing a receiving scale, the lever OM may be prolonged to e right, and graduated as a steelyard. And in machi s where an upward instead of a downward pressure is giv at M, the lever OM is prolonged to the left, and the ful um L and its resting-block removed to N.

achines consisting of variously modified systems of lev s have been used for a considerable period. The one ab e described is that generally employed. The arrangeme of the levers is well conceived, and exactly suited for the urpose to which the machine is now chiefly applied. Its rst contrivance and employment is said to have been for eighing the riders of race-horses.

e beam of this balance consists of two rods, at some dis nce apart, but united so as to move together. The sca s are supported above this rectangular beam; the rising nd sinking of the frames in which they rest, and by wh h they bear on the knife-edges at each extremity of the beam, being regulated by a parallel movement, the lev s of which are placed in the stand of the balance. It is derstood to have been of French invention, and is a co enient form of machine; but the bearings, which are nu erous, and liable to be somewhat displaced, give rise to co derable friction, and occasionally to slight derangeme s of the leverage. Some improvements on it in these res ects were patented by Mr Poupard of ondon. In his machine there are sti however three parallel knife-edge be ngs, three circular ones, and other so ces of friction, which, from the constr tion necessary for the proper ascent an descent of the scales, cannot be av led. The working parts of the machine are mostly ca d up to protect from dust. In the annexed figure, so of these casings are omitted, that the representation ma be properly intelligible.

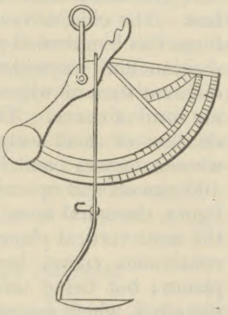


II. *Self-adjusting Balances, which derive their Power of progressive Resistance from Properties strictly mechanical.*

Under this head we place Ludlam's balance, introduced about 1760, and an improved modification of it, named the bent lever. Ludlam's is described under MECHANICS, p. 371, and the bent lever under the article BALANCE.

Brady's domestic balance.

This balance, by Mr Brady of London, is provided with different points of suspension for the scale, and is a modification of the bent lever one. In the upper end of its lever are three cavities, at different distances from the centre of movement, from any of which the scale may be hung. For each cavity there is a separately graduated arc. The three arcs are placed one above another, and move through an opening in the bar or shears which carries the receiving scale, the edge of the bar serving the purpose of a pointer. When the scale is hung from the cavity next the upper end of the lever, the beam becomes horizontal, each ounce, as far as two pounds, being indicated on the upmost arc. When hung from the middle cavity, each alternate ounce, as far as eleven pounds, is indicated on the middle arc; and when hung from the remaining cavity, each quarter pound, as far as thirty pounds, is indicated on the lowest arc. In point of principle it differs from the bent lever thus far, that the acting mass of the counterpoise is altered (for the most part increased) by the accumulating weight of the graduated arcs and their strengthening stays as they pass the vertical line from the centre.



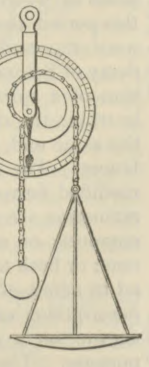
Dampier's patent geometrical balance.

The balance by Mr Dampier of Ware is in this respect the reverse of Mr Brady's. Here a circular disc or wheel is employed, which, as it turns on its centre, is balanced in any position, and therefore neither adds to nor diminishes the acting mass of the counterpoise, which is hinged on a round stud placed in the rim of the disc. The scale is similarly attached to the rim of the disc, a little more than a quarter circumference intervening between the two studs. The pointer is formed in the suspending frame or stand which supports the axis, and the graduations are marked on the upper part of the circle. This construction is a modification both of the bent lever and Ludlam's balance, and, in cases where the weights to be examined are of small amount, is preferable to the former.

The foregoing self-adjusting balances are placed together, as being nearly allied, and having a similar extent of movement, viz. something short of a quadrant.

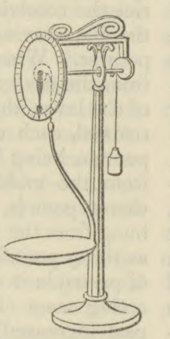
Lothian's patent revolving balance.

In this balance (manufactured by Messrs Milne, Edinburgh), the opposing arms are formed of grooved eccentric, or spiral curves. These are acted on by the cords or flat chains which suspend the counterpoise and receiving scale, and are thus caused to move round on their common axis, which is placed in the pole of the curves. In the annexed figure the dial is supposed to be transparent, and being fixed in front to the curved balance, moves along with it. The pointer is stationary, and is fastened to the shears or fork which suspends the balance, and indicates on the dial as it passes round. By the changes of leverage which occur in the course of revolution, the counterpoise rises from a small power to a greater; while the scale, in proportion as it becomes loaded, contracts throughout from a greater leverage to a less. This general



Weighing Machines.

principle of combined changes of leverage affords a favourable means of employing an unchanging weight to balance others, both greater and less than itself; and at the same time admits of the parts necessary to produce powerful and sustained resistance being practically formed within convenient compass. The self-adjusting power thus generally obtained is regulated in the rate of its increase by a definite construction of the curves, which are formed to cause equable as well as progressive resistance, by which means the balance is moved through equal angles by equal weights. The graduated scale extends to three quadrants, more or less. The chief advantage of the balance is, that it combines this lengthened primary movement with equable graduation and unyielding mechanical construction. The different sizes of which it is made have each an appropriate form of curve. The least is fitted for the minute subdivision of small weights; the next indicates to four or sixteen ounces; and larger sizes range to twenty, fifty, 100 pounds and upward. In the adjoining figure, the spiral arms, which before are in the same vertical plane, and merge into one continuous curve, here occupy different planes; but being united by an intermediate rod, which passes through the upright of the stand, they have simultaneous movement. The dial is fixed to the bearing-frame, and the pointer is carried round by the axis. The graduation, which in this form may be prolonged to any desirable extent, occupies a full circuit. In other respects, the description already given is alike explanatory of both balances. There are some minutiæ which give refinement to their action; but as these are used only in particular machines, they are not represented, and need not be described in detail. A delicately constructed modification of the instrument is also arranged to shew, on inspection, and without the use of eke-weights, the specific gravities and weights per cubic inch of different fluids.



III. *Self-adjusting Balances, which derive their resisting Power from the Elasticity of Metals.*

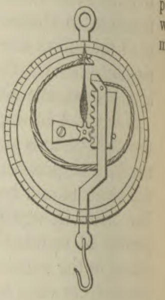
Under this head may be mentioned Coulomb's torsion-balance, formed of brass wire, the twisting and untwisting of which is applied to the measurement of small forces. It is described under Balance, p. 307, Hydrodynamics, p. 76, and Mechanics, p. 401. The dynanometer for the measurement of larger forces, and applicable also to the ascertainment of weight, is explained at the conclusion of the article Dynamics. That of Mr Veitch is represented and described in the article Agriculture, p. 355.

Spring steelyard or balance.

The spring is supposed to have been applied to the purposes of weighing about the year 1690 or 1700. About this period the dynanometers of Graham and Desaguliers were superseded, first by Monsieur Leroy's of the Academy of Sciences, who applied to the purpose the compression of a spiral spring; and next by Monsieur Regnier's, in which the distention of an elliptical one was adapted to the same end, both springs being then also in use as balances. The spring-balance is constructed in a variety of modified forms; but in all of them the weights under examination are caused either to bend a plain spring, or to compress or extend an elliptical, semi-elliptical, or spiral one; or both to compress and extend the spring when formed to admit of this. The amount to which any of these descriptions of spring yields to different stated weights, is shewn on a graduated scale properly situated for the purpose. The principle of extension is preferable to the other, inasmuch as it is put in operation by simpler and less complex means; and when the weights to be examined are large, the elliptical spring should be adopted; but when these are of a moderate amount, the spiral form is best. For many purposes the spring-balance is a convenient instrument, but not a lasting one. The spring, when fresh and unused, is equable in its successive yieldings, but is liable to variations, which cause it gradually to lose correspondence with the divisions. It is affected by temperature, and weakened by use; and if overstrained or corroded, its power and quality are materially changed. In some balances an extra spring is introduced to adjust these irregularities; but this should be omitted, as its operation increases the chance of error, without removing the cause; for though the pointer, when displaced, may be restored by it to zero, there are then two acting springs changed in position, quality, and strain, while the line of graduations remains as it was derived from the original elasticity of the leading spring.

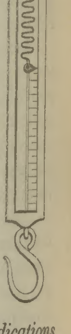
Mar pate weig mac

In this balance, by Mr Marriott of London, the spring is formed into an arbitrary curve, and is placed in a shallow brass box behind the dial, which latter is here supposed to be transparent; one end of the spring is fixed to the upper side of the box, and the other end to the head of the rod which carries the hook. Near the same point of this rod is also attached the head of the rack-plate, which, as the hook becomes loaded, is lowered by the spring and turns the pinion, and with it the pointer, which indicates the weight. When in use, the portion of the spring to the left is extended, and that to the right compressed; and during descent, the rack is kept in gear with the pinion by a screw-pin at its right side.



Salte impr sprin lance

This balance, by Mr Salter of London, is represented in the annexed figure, the index-plate in front being supposed transparent. It is formed of a spiral spring, which is contained in the upper part of a cylindrical case, behind the index-plate. One extremity of the spring is fastened at the head of the instrument, and the other extremity is fixed to the rod which carries the pointer and the hook or scale. The spring extends in proportion as the hook is loaded; the pointer at the same time shewing the weight on the graduated front. Mr Salter subsequently made some alterations, which he patented; most of them however relate to minor details, and need not be described.

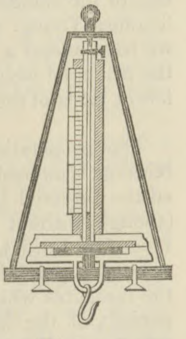


IV. *Self-adjusting Balances, whose progressive Indications are regulated by the Properties of Fluids.*

Under this head may be included several of the various instruments for ascertaining specific gravities, which are described under Hydrodynamics, p. 22–25. Although most of these require eke-weights to complete their range of indications, they are nevertheless of self-adjusting character; their principle of adjustment depending on the different depths to which fluids of varied density permit the graduated stem of the instruments to sink. Here also may be mentioned Mr Harris's electrometer, described under Electricity, p. 658, a balance in which the resistance is obtained by the accumulating power which an elongated counterpoise acquires when caused to emerge from a fluid; the same principle being further illustrated under the article Gas-Light, p. 353–54, where its application to the progressive balancing of the gasometer is explained.

This balance, by Mr Hawkins of London, consists of a cylindrical vessel open at top, on the face of which is a vertical glass tube also open above, and entering the cylinder near its base. Within this outer case is another hollow cylindrical drum, of rather smaller diameter, on the top of which is placed the receiving scale. The inner cylinder floats on the water which the outer one contains. In proportion as the scale is loaded, the water rises between the cylinders and in the glass tube, beside which is a graduated scale, the weight being indicated by the height which the fluid attains in the tube. The water carried off by evaporation should be replaced, as much being poured in from time to time as is required to preserve its surface at zero when the scale is empty. The continual effort of the inner cylinder to escape to the sides of the outer one is, however, a source of considerable friction; a slight displacement of the cylinder from the horizontal position, or the loading of the scale more on one side of its centre than another, contributing to augment the evil.

This balance, by Mr Bursill of Islington, is formed in a variety of different modifications; some of them depending on a stem or piston being caused to sink in a fluid, and others on its being caused to rise from one. It may however be generally described as consisting of two cylinders of different diameter united by a connecting tube. From the top of the smaller cylinder rises a glass tube, at the side of which is a moveable index-plate, on which the graduations are marked. Mercury is poured to some depth into the cylinders, the smaller of which, together with the lower part of the glass tube, is then filled up with oil or coloured water, which rests on the surface of the mercury. A piston or stem, guided by a parallel movement, rises and falls in the larger mercurial holder. A counterpoise on one of the parallel rods balances the weight of the scale; and when the latter is loaded, the displacement of mercury in the larger cylinder causes the water to rise in the tube by more perceptible gradations, and indicate the weight. This balance is likewise arranged in various combinations with the steelyard, and two contrivances (one of which may be added to the machine) are provided with the view of compensating the irregularities caused by change of temperature. The cylinders for the mercury are formed of pipe-clay; and a stop-cock is placed at the head of the tube, to be opened during use to admit air, and closed afterwards to exclude dust and diminish evaporation.



This machine, by Captain Ericson of London, is represented in the annexed figure. It consists of a shallow circular box of cast iron, formed of two portions, an upper and under one; the interior diameters of which are somewhat different. The lower half of the box contains a piston, the neck of which passes freely through an aperture in the bottom, and is screwed to the horizontal bar of the triangular suspending frame. A circular piece of India rubber cloth is laid over the face of the piston, and continued through between the joining rims of the iron box, the halves of which are then screwed together upon it. From the upper half of the box rises a hollow iron stem, sufficiently laid open to expose to view a glass tube, which it encloses in a bed of Paris plaster. Mercury is then introduced through the tube into the upper half of the box; and its escape being prevented by the cloth, and the distention of this resisted by the piston, the box and stem are set afloat, and are kept from capsizing by a small pin from the top of the triangular frame, which enters into the bore of the upright stem. The hook is connected with the box, and, on being loaded, draws it down, thereby causing the ring of cloth exterior to the circumference of the piston to descend below the piston's surface;—in effect thus contracting the space in the box, and forcing the mercury up the tube till it indicates the weight on the graduated scale. Two safety-screws in the lower bar are adjusted to prevent the box from descending so far as to eject the mercury from the tube; and, as in Mr Bursill's, a stop-cock is placed at the mouth, to be opened during use to admit air, and shut after it to exclude dust and diminish evaporation. In this machine, the primary movement must necessarily be extremely confined (about the 50th or 100th part of an inch), otherwise the cloth, by being overstretched, would give way. Any deviation from uniform action, however arising, and however trifling, is thus apt to occasion a magnified irregularity in the indication. The admission of dust and evaporation of mercury; the effort made by this fluid at all points to draw into globular formations, and avoid the minuter recesses of the holder; the change of temperature, and progressive distention and wrinkling of the cloth, are among the more immediate and least controllable sources of variation.

V. *Letter and Post-Packet Balances.*

Under this general title are enumerated such of the preceding as are applied to the purpose of weighing letters; descriptions of the balances not yet noticed being subjoined.

1. The Common, the Roman, and Danish balances; 2. the Bent-lever, Brady's, Dampier's, and Lothian's balances; 3. Salter's and other Spring-balances; 4. Bursill's balance, all as above described, are constructed also of sizes suited for letter-weights.

Robison's mercurial letter-balance.

In this balance, which was devised for letter-weighing by Sir John Robison, secretary to the Royal Society, Edinburgh (and made by Mr Forbes there), the letter is placed on a circular ivory disc, which is supported by a steel wire, that passes freely through a small orifice in the ivory cap of a glass tube filled about a third of its depth with mercury. To the lower end of the wire is screwed a cylindrical ivory stem of larger diameter than the wire, and marked with circular graduations. This sinks in the fluid in proportion as the disc is loaded; and the vertical movement is preserved by guide-pins, which diverge from the lower extremity of the stem. A loose ring of ivory serves the purpose of a floating pointer, while it prevents the eye being deceived by the glance of the fluid, or the images occasioned by its reflecting powers. Shortly afterwards, letter-balances of similar description were made by Messrs Miller, Dundee; Lund, Fleet Street; Osler, Birmingham; and Bursill, Islington; the three latter being registered designs.

Miller's, Lund's, Osler's, and Bursill's balances.

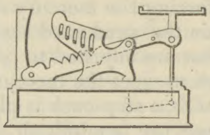
The remaining balances may properly be arranged by themselves, as a class formed to indicate periodical amounts of weight, but not their intermediate subdivisions.

Riddle's and Gye's registered letter-balances.

In the balance by Mr Riddle of London, weights of an ounce each are rested on the successive steps of a pyramidal support. A ring attached to one arm of a balance lifts the lowest, and proceeds to the others in their order; the postage corresponding to the number of weights raised being indicated by a pointer. In Mr Gye's balance three rings fixed at proper heights give support to as many weights, which are attached by a small chain to the arm of a balance, each weight being lifted in succession, and the postage known by the number of weights raised. Mr Riddle's arrangement, however, provides for a more exact movement.

Willis's patent letter-balance.

This balance, by Professor Willis, Cambridge (made by Messrs Hotzapffel), is formed of two beams joined at some distance apart, so as to form a rectangular frame, which the figure of Poupard's balance above described will serve to illustrate. Here also, as in that balance, the receiving scale is placed above the beam, and is similarly guided in its descent by a parallel movement placed in the stand. The two beams are angularly notched in the manner shewn in the adjoining figure, which represents a side plan of the balance. Five cylindrical bars of adjusted weight rest in the arms of a rack, which supports them horizontally across each pair of notches, and at increasing elevations from the stand. These bars successively take their appropriate place on the double beam, and are each lifted by, and become as it were a part of it, so soon as the load placed on the scale exceeds the stated amount. Thus, when a letter exceeds half an ounce, the beam rises to, but does not lift, the first bar; when it exceeds an ounce, it lifts the first, and rises to, but does not raise, the second; and so on to the fifth. When it exceeds this, an eke-weight which accompanies the machine is placed in the square-shaped notches at the extremity of the beam, and five ounces or their corresponding postage are added to the subsequent indications of the balance, which anew traces the same progression. The weights or postages are marked on an upright which is fixed at one end of the stand, and are pointed out by a wire extended between the two beams of the balance.



Freeman's patent letter-balance.

In this balance, by Mr Freeman, Sutton-Common, there are various fixed angular fulcra and a constant weight. The beam, which is loaded at one end, rests on the angular fulcrum nearest the weight. The fulcrum is supported at each end by a frame which rises from the top of a pillar. The upper surfaces of the two supporting frames are obtusely rounded, and notched at intervals suited to receive each fulcrum in its turn. When a letter exceeds a half ounce, the beam turns on, but does not quit, the first fulcrum. When it exceeds an ounce, it turns on, but does not quit, the second, and so on; the resting extremities of each successive fulcrum taking their appropriate place in a new pair of notches, and a pointer below shewing the result. This balance in general conception is a counterpart, or very nearly so, to Mr Willis's, but is one which perhaps scarcely admits of being practically formed for very effective operation.

The theory of balances depending on the properties of the lever is given at large under the articles MECHANICS, pp. 358, 370, and BALANCE; that of the spring is illustrated under MECHANICS, p. 402; and the theory of those depending on the properties of fluids is fully explained under HYDRODYNAMICS, pp. 13, 14, and 19–25. (D. I.)

WEIGHT, in *Physics*, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined, in a less limited manner, to be a power inherent in all bodies, whereby they tend to some common point, called the *centre of gravity*, or, to speak more accurately, to one another; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare.

WEIGHTON, or MARKET-WEIGHTON, a market-town of the east riding of the county of York, in the wapentake of Harthill, 192 miles from London and eight from Beverley. It chiefly consists of one long street, with a few of less appearance leading from it. It has a good corn market on Wednesday, and a canal communication with the Humber through the Ouse. The population amounted in 1821 to 1724, and in 1831 to 1821.

WEIGHTS AND MEASURES.

By *weight*, or, as some call it, the *measure of weight*, is meant the apparent force or tendency which any body or commodity has to descend; and which, owing to the centrifugal force of the earth's rotation, and the buoyancy of the air or other medium in which the operation of weighing is performed, is somewhat less than its real force, the latter being always proportional to the intensity of gravity multiplied by the mass weighed. Accurate weighing is of great importance, since in general it affords one of the best practical means of ascertaining the quantity of matter in bodies, and thence the values of the greater part of the necessaries of life. But although, in most cases, the buoyancy of the medium may have some effect, however small, it is evident that any difference in the intensities of gravity, or of centrifugal force in different latitudes, or even on different planets, can, *cæteris paribus*, make no difference on the weights of bodies as obtained by counterpoising; but the weight, when indicated by the force or resistance of a spring, will, *cæteris paribus*, be proportional to the intensity of gravity. The term *measure* in the present article more properly applies to the three following kinds of magnitudes, sometimes called geometrical: 1st, linear extent, such as the length or other linear dimensions of bodies; 2d, area, surface, or superficial extent; 3d, the bulk of bodies, or the solid space occupied by them, and which, when spoken of the vessels which measure or contain them, is called their contents or capacity. This article then is meant to treat of the usual standards of weights and measures, by comparison with which the amount of any article or commodity is ascertained, whether in the ordinary affairs of life, the more extensive transactions of commerce, or where greater nicety is required in the arts and sciences. Anciently standard weights or counterpoises were generally of stone, though sometimes of metal. At present mostly all the smaller standard weights are made of some metal possessing such a composition and hardness as may be less liable to be worn or corroded, counterfeited or altered; and one of the best is a mixture consisting principally of copper and tin. The larger weights are generally of iron, though sometimes of stone. The more accurate standards of length are likewise of metal, but the larger sort is very generally of wood: chains, cords, and tapes are also used. The nicer measures of capacity are formed of metal or glass, but the larger and more common sort is mostly all of wood. After what immediately follows on the equalization of the standards in the British empire, by the late Dr Thomas Young, and his very compendious general table, we have added a more particular though brief account of the principal weights and measures at present used in different parts of the world.

The preparation of the bill for ascertaining and establishing Uniformity of Weights and Measures, which passed the Imperial House of Commons in the session of 1823 (though without having been then carried through the House of Lords), had given occasion for a laborious and somewhat painful examination of the historical progress of the measures which have been taken respecting it, and especially of the laws of England respecting uniformity of practice in different parts of the country; for such a uniformity, though generally esteemed by all governments a thing to be encouraged and enforced, had often seemed to be no more subject to the control of legislative enactment than the introduction of a uniformity of language and a grammatical accuracy of speech would be found in every part of an extensive empire.

Augustus is said to have endeavoured in vain to force a new Latin word into the language of ancient Rome: the

French, on the other hand, after all their labours to recommend a uniform system of measures, have ended in such a complication, that, for the most simple purposes of practical mechanics and civil life, it is become usual to carry in the pocket a little ruler, in the form of a triangular prism, one of the sides containing the old established lines and inches of the royal foot, a second the millimetres, centimetres, and decimetres of the revolutionary school, and the third the new ultra-royal combination of the Jacobin measure with the royal division, the inches consisting of the 36th part of a metre, or the four millionth of a degree of the meridian of the earth. If such occurrences as these be calmly considered, they will make us more disposed to diminish than to increase the number of penal statutes intended to compel the inhabitants of the different parts of a country to study their own convenience conjointly with that of their neighbours, and to spare themselves the necessity of a few arithmetical operations in the course of every market-day; and we shall feel that it is more incumbent on a wise government to endeavour to facilitate both the attainment of correct and uniform standards of legal existing measures of all kinds, and the ready understanding of all the provincial and local terms applied to measures, either regular or irregular, by the multiplication of glossaries and tables for the correct definition and comparison of such terms.

Measures have apparently always been derived, in the first instance, from some part of the human person. A foot, a pace, a fathom, the orgyia or stretch of the arms, a cubit, a palm, and a finger; these have probably all been used in the earlier states of society by each individual from the magnitude of his own person; and afterwards a standard measure has been established by authority from the real or supposed magnitude of the person of some king or hero, in order for the attainment of more perfect uniformity in practice; though it is said, that in some parts of the East the Arabs still measure the cubits of their cloth by the fore arm, with the addition of the breadth of the other hand, which serves to mark the end of the measure, as the thumb which was formerly added at the end of the yard by the English clothiers. It ought not however to be forgotten, that any one of these terms possesses an advantage for popular use, and for the convenience of future ages and of remote countries, which would be lost by the introduction of any more arbitrary measurement. Thus a hand's breadth, or a foot, is always sufficiently understood, without any definition, to enable us to form to ourselves a tolerably accurate picture of the magnitude intended to be described; and there is scarcely an instance of the caprice of denomination having ever extended so far as to make the measure called a foot in any country so small as half a natural foot, or so great as two feet of an ordinary person, and certainly not of its amounting to three ordinary feet; while a metre, even to those who know that the word implies a measure, might as well have meant a mile, or an inch, or a quart, as a length somewhat greater than a yard.

The idea of accurately verifying the standard of a country by any other means than that of a comparison with some actually existing original, can scarcely have occurred, except in a very advanced period in the progress of civilization. It was indeed enacted in the time of our Henry the Third, that an ounce should be the weight of 640 dry grains of wheat taken from the middle of the ear, that a pound should be twelve ounces, a gallon of wine eight pounds, and eight gallons of wine a bushel of London; but this seems rather a direction for making a single standard than a mode intended for the continual verification of the standard in case of any minute uncertainty. Again, in a statute of Henry the Seventh, a gallon of corn was mentioned as containing eight pounds of wheat: and this may perhaps serve to explain the origin of the two different gallons. But the substitution of an original standard derived from an object of definite magnitude, exterior to the human person, seems to have been reserved for the days of the French revolution, though it has since been adopted in an improved form by the introduction of a foot equal to $\frac{12}{38}$ of the pendulum vibrating seconds, as a representative of the customary foot of the kingdom of Denmark. (Quarterly Journal of Science for 1821, *Astr. Coll.* No. V.)

The Royal Society, under the presidency of Mr Folkes, made some very accurate comparisons of the English, and French, and old Roman standards, which are recorded in the Philosophical Transactions for 1736, 1742, and 1743; and George Graham, the eminent watchmaker, determined at the same time the length of the pendulum vibrating seconds to be 39·130 inches; but the standard with which he compared it requiring some reduction, it was afterwards ascertained that the length, as derived from these experiments, ought to have been more nearly 39·14 inches.

A committee of the House of Commons was appointed in 1758, of which Lord Carysfort was chairman. Their Report contains some important information respecting the standards then in use. They found that the customary ale and beer gallon of the Excise was estimated at 282 cubical inches, while the legal wine gallon of the Exchequer was computed at only 231, though the only existing standard of the wine gallon in 1688, which was kept at Guildhall, contained no more than 224 cubical inches. They suggested the adoption of this smaller gallon for the legal standard, perhaps as being more favourable to the revenue, though the gallon of 231 inches had been previously legalized by the act of the fifth of Queen Anne; and they employed the well-known Mr Bird to prepare two standards, which were to be exact copies of that which was made by Graham for the Royal Society in 1742, from a very careful comparison of the various yards and ells of Henry the Seventh and Elizabeth, which were kept in the Exchequer. One of the copies was marked "Standard Yard, 1758," and was presented by the committee to the House with the intention that it should be adopted as the legal standard; the other was made "with cheeks" for common use, and proposed to be kept in the Exchequer.

A subsequent Report of a committee appointed in 1759, consists principally of proposals for some legislative regulations, tending to facilitate the equalization of weights and measures by the establishment of proper methods of checking and authorizing the standards to be employed. In 1765, two bills were brought into the House of Commons by Lord Carysfort, in conformity with the Reports of the committees; but, from some accidental circumstances, they were not passed into laws.

Another committee was appointed in 1790; but no minutes of their proceedings have been recorded. In 1814 however a very important Report was presented to the House by a new committee, who had called upon Dr W. Hyde Wollaston and Professor Playfair for their opinions on the subject; and it was principally in consequence of these examinations that the committee stated that the length of the pendulum vibrating seconds had been ascertained to be 39·13047 inches, and that the metre of platina measured, at the temperature of 55°, 39·3828 English inches, representing at 32° the ten millionth part of the quadrant of the meridian. They remarked with great truth, that although in theory the original standard of weight is best derived from the measure of capacity, yet in common practice it will generally be found more convenient to reverse this order; and they recommended, upon the suggestion of Dr Wollaston, that a gallon containing ten pounds of pure water should be adopted as a substitute for the ale and corn gallons, which had become different rather from accident than from any direct legislative authority, the one containing a little more than ten pounds, the other a little less, though the standards of the latter were extremely discordant among themselves. It seems to have been intended to abolish the wine gallon, which is also that of the apothecaries; though it was recommended to retain the use of the Troy weight of the goldsmiths, employed also by the apothecaries. It had before been observed, that twelve wine gallons of distilled water weighed exactly 100 pounds avoirdupois; but Dr Wollaston's proposal to make an ale gallon exactly of ten pounds, afforded a greater facility in the operation of adjusting the measure, since it is not very easy to divide 100 pounds into twelve equal parts, with the weights in common use.

Some very important experiments on weights and measures had been made a little before the date of this committee, by Sir George Shuckburgh Evelyn, who had published an elaborate paper on the subject in the Philosophical Transactions for 1798; and by the ingenious Mr Whitehurst, who obtained the length of the pendulum by measuring the difference of two lengths affording vibrations of different frequency. There were still some minute discordances between the various measurements which appeared to be of the highest authority; and some particulars in the Report of the committee of 1814 are manifestly erroneous. Thus the weight of a cubic foot of water is stated, from a mistake in computation, to be 1000 ounces at $56\frac{1}{2}$° of Fahrenheit, while, in fact, it is less than this even at 39°, the maximum of density; and again, the customary length of the English foot, which has always been adjusted at the ordinary temperature of the atmosphere, and rather at that of the summer than that of the winter, as, for example, in the great trigonometrical operations of General Roy and his successors, at 62° of Fahrenheit, was, in the experiments, copied by the committee from Pictet, compared with the French standard, which was intended to be employed at the freezing point of water, without any correction for this diversity; though Dr Young had long before pointed out the omission both in the Journals of the Royal Institution and elsewhere, and had computed the true length of the metre according to these operations of Professor Pictet, confirmed by some earlier ones of Bird, Maskelyne, and Lalande, to be 39·3710 English inches, instead of 39·3828.

In order, therefore, to remove any doubt which might still be reasonably entertained on the subject, Mr Davies Gilbert moved the House of Commons, in the year 1816, to present an humble address to the prince regent, praying that he would give direction that proper measures should be taken for ascertaining the length of the pendulum vibrating seconds, and for comparing the French and English standards with each other. In consequence of this address, the astronomer royal was in the first instance directed to perform the necessary operations; and, upon his asking for some further assistance, the president and council of the Royal Society were requested to appoint a committee to co-operate with him. This committee consisted, besides the president and secretaries, of the late Sir Charles Blagden, Mr Gilbert, Dr Wollaston, Dr Young, Captain Kater, General Mudge, Mr Brown, Mr Rennie, and Mr Troughton. They began by discussing the several modes of making the requisite experiments which occurred to the different members; and it was resolved, that as many of these methods as were preferred by each of them, should be separately carried into execution, in order to obtain collateral determinations of the required length. Mr Pond pursued the method of the French astronomers, and obtained some very satisfactory results, with an apparatus such as they had employed; Dr Young proposed a method derived from that of Whitehurst, and very perfect in theory, but somewhat complicated, and which has never yet been practically executed; Captain Kater invented, with great ingenuity, and employed, with great mechanical skill, an apparatus which does as much credit to his talents in the arrangement as to his perseverance in the experiments which he performed with it, and the accuracy of his determinations has been fully appreciated by mathematicians and practical astronomers throughout the world; and his operations have been repeated by many observers in different countries. Captain Kater's apparatus has been described in the article Pendulum. It owes no inconsiderable part of its advantage to the property supposed to have been subsequently demonstrated by Laplace, that, even if the opposite knife edges were considerably blunted and rounded off, supposing both to be equally affected, the distance between them would still afford the true measure of the length of the pendulum without any further correction for the change of the axis of motion. [But that this celebrated property, after all, is only true within certain limits, has been shewn in the article Pendulum, vol. xvii. p. 210.] It has also been demonstrated in this country by means of the experiments of Chladni on the elasticity of metals, that the temporary change of form depending on the compression of the steel edge, would be too inconsiderable to produce any sensible alteration of the length in question.

The object of Dr Young's apparatus was to obtain two or more fine lines, traced at different parts of a scale, which should exhibit between them a certain determinate portion of the length of a pendulum vibrating seconds. He apprehended that the accurate determination of the form and direction of the knife edges, and the measurement of the distance between any such edges, which was necessary in the method proposed by Prony, as well as in that which was subsequently invented by Captain Kater, would require more skill and delicacy in the execution and the observation than could be expected from any common workman or experimenter; and though Captain Kater, by his extreme care in combating every source of error, has, in point of fact, apparently obviated all these difficulties, yet it cannot be expected that so rare a combination of qualifications should again be found, in case of a repetition of the experiments, and Dr Young's apparatus may still, at some future time, be employed with advantage, at least for a collateral check upon the results.

The obstacle which prevented the completion of the observations which were made for some time with this apparatus at Greenwich, was the difficulty of obtaining a scapement so delicate as to count the number of vibrations, without sensibly interfering with their frequency. A very ingenious clockmaker was employed to furnish a scapement, of which the intention was to strike the pendulum slightly and instantaneously at the lowest point of its vibration, and then to recoil from it, so that even a considerable impulse might have little or no effect in altering the rate of the pendulum; but it was in fact observed, upon comparison with the clocks of the observatory, that the vibrations in larger arcs were more frequent than those which were performed in smaller; so that the scapement must have exerted a very considerable influence on the time of every vibration. It was therefore found necessary to abandon this method of making the experiment; but there would be no difficulty in conducting it very satisfactorily by means of a journeyman clock, with a wooden or brass pendulum, capable of having its length altered so as to become comparable with the vibrations of Dr Young's pendulum in its different states; and it might even be found sufficient to observe the pendulum, with the same scapement, so altered as not to give any impulse whatever, but merely to reckon the vibrations by means of the detent during the spontaneous vibrations of the pendulum, which, on account of its great weight, would be continued for a considerable time in consequence of the first impulse, taking care that the detent should be struck exactly at the middle of the vibraion, and that it should rebound in some measure from the pendulum at the moment of contact.

Before any attempt was made to introduce any legislative regulations upon the foundation of the various scientific experiments which had been so accurately and satisfactorily conducted, it was thought advisable by his majesty's ministers that the subject at large should be submitted to the deliberate consideration of some competent persons, who might discuss it more minutely than could be done with convenience before a committee of either house of parliament; and that a commission should be appointed for this purpose, by a writ of the privy seal. The commissioners thus nominated in 1818 were, Sir Joseph Banks, Sir George Clerk, Mr Davies Gilbert, Dr W. Hyde Wollaston, Dr Thomas Young, and Captain Henry Kater. Some further operations for the comparison of the existing standards of length were undertaken by Captain Kater. [Since this article was first published, Captain Kater has, in the Philosophical Transactions for 1826, given a detailed account of these operations; and in the Philosophical Transactions for 1830 and 1831 he has pointed out a variety of nice adjustments and corrections to be made on them, which fortunately are too minute to affect any ordinary weights or measures. But Mr Sang has lately communicated to the Edinburgh Society of Arts a notice of some defects in these last corrections of Captain Kater.] Dr Wollaston examined some of the authorized measures of capacity, and Dr Young offered his services as secretary to the committee, with the assistance of a clerk who had studied the law, while Sir George Clerk and Mr Gilbert were employed in preparations for carrying into effect, in their legislative capacity, such regulations as the commissioners at large might agree to propose. The first occupation of the clerk was to make copious extracts from the statutes at large, by means of which Dr Young drew up an abstract of the present state of the laws relating to weights and measures; and the next to select from the agricultural reports of the different counties such materials as afforded a glossary of all the terms employed in any part of Great Britain for denominating the irregular weights or measures which have acquired a local currency in the agricultural or other commercial transactions.

After this sketch of the previous history of the subject, we may now proceed to extract from the Reports of the Commissioners, and from the bills founded on them, such statements as may either serve in the place of canons for the regulation of weights and measures in general, or as documents respecting the actual value of the various standards possessing the highest degree of authenticity; and this article cannot be more properly concluded than by subjoining some further comparative tables of the standards of measures and weights adopted by different countries and at different periods.

First Report.—" I. Upon a deliberate consideration of the whole of the system at present existing, we are impressed with a sense of the great difficulty of effecting any radical changes, to so considerable an extent as might in some respects be desirable; and we therefore wish to proceed with great caution in the suggestions which we shall venture to propose.

" II. With respect to the actual magnitude of the standard of length, it does not appear to us that there can be any sufficient reason for altering those which are at present generally employed. There is no practical advantage in having a quantity commensurable to any original quantity existing or which may be imagined to exist in nature, except as affording some little encouragement to its common adoption by neighbouring nations. But it is scarcely possible that the departure from a standard, once universally established in a great country, should not produce much more labour and inconvenience in its internal relations than it could ever be expected to save in the operations of foreign commerce and correspondence, which always are and always must be conducted by persons to whom the difficulty of calculation is comparatively inconsiderable, and who are also remunerated for their trouble, either by the profits of their commercial concerns, or by the credit of their scientific acquirements.

" III. The subdivisions of weights and measures at present employed in this country appear to be far more convenient for practical purposes than the decimal scale, which might perhaps be preferred by some persons for making calculations with quantities already determined. But the power of expressing a third, a fourth, and a sixth of a foot in inches without a fraction, is a peculiar advantage in the duodecimal scale; and, for the operation of weighing and measuring capacities, the continual division by two renders it practicable to make up any given quantity with the smallest possible number of standard weights or measures, and is far preferable in this respect to any decimal scale. We would therefore recommend that all the multiples and subdivisions of the standard to be adopted should retain the same relative proportions to each other as are at present in general use.

" IV. The most authentic standards of length which are now in existence being found, upon a minute examination, to vary in a very slight degree from each other, although either of them might be preferred, without any difference that would become sensible in common cases; we beg leave to recommend for the legal determination of the standard yard that which was employed by General Roy in the measurement of a base on Hounslow Heath, as a foundation for the trigonometrical operations that have been carried on by the Ordnance throughout the country, and a duplicate of which will probably be laid down on a standard scale by the committee of the Royal Society appointed for assisting the astronomer royal in the determination of the length of the pendulum; the temperature being supposed to be 62 degrees of Fahrenheit when the scale is employed.

" V. We propose also, upon the authority of the experiments made by the committee of the Royal Society, that it should be declared, for the purpose of identifying or recovering the length of this standard, in case that it should ever be lost or impaired, that the length of a pendulum vibrating seconds of mean solar time in London, on the level of the sea, and in a vacuum, is 39·1372 inches of this scale; and that the length of the metre employed in France, as the 10,000,000th part of the quadrantal arc of the meridian, has been found equal to 39·3694 inches.

" VI. The definitions of measures of capacity are obviously capable of being immediately deduced from their relations to measures of length; but since the readiest practical method of ascertaining the magnitude of any measure of capacity is to weigh the quantity of water which it is capable of containing, it would, in our opinion, be advisable in this instance to invert the more natural order of proceeding, and to define the measures of capacity rather from the weight of the water they are capable of containing, than from their solid content in space. It will therefore be convenient to begin with the definition of the standard of weight, by declaring that 'nineteen cubic inches of distilled water, at the temperature of 50°,' must weigh exactly ten ounces troy, or 4800 grains, and that 7000 such grains make a pound avoirdupois; supposing, however, the cubic inches to relate to the measure of a portion of brass, adjusted by a standard scale of brass. This definition is deduced from some very accurate experiments of the late Sir George Shuckburgh on the weights and measures of Great Britain; but we propose at a future period to repeat such of them as appear to be the most important.

" VII. The definitions thus established are not calculated to introduce any variation from the existing standards of length and of weight, which may be considered as already sufficiently well ascertained. But with respect to the measure of capacity, it appears from the Report contained in the Appendix (A), that the legal standards of the highest authority are considerably at variance with each other; the standard gallon, quart, and pint of Queen Elizabeth, which are kept in the Exchequer, having been also apparently employed, almost indiscriminately, for adjusting the measures both of corn and of beer; between which however a difference has gradually, and, as it may be supposed, unintentionally, crept into the practice of the excise; the ale gallon being understood to contain about four and a half per cent. more than the corn gallon, though we do not find any particular act of parliament in which this excess is expressly recognised. We think it right to propose that these measures should again be reduced to their original equality; and at the same time, on account of the great convenience which would be derived from the facility of determining a gallon and its parts, by the operation of weighing a certain quantity of water, amounting to an entire number of pounds and ounces without fractions, we venture strongly to recommend that the standard ale and corn gallon should contain exactly ten pounds avoirdupois of distilled water at 62° Fahrenheit, being nearly equal to 277·2 cubic inches, and agreeing with the standard pint in the Exchequer, which is found to contain exactly twenty ounces of water.

"VIII. We presume that very little inconvenience would be felt by the public from the introduction of this gallon in the place of the customary ale gallon of 282 cubic inches, and of the Winchester corn gallon, directed by a statute of King William to contain 269, and by some later statutes estimated at $272\frac{1}{4}$ cubic inches; especially when it is considered that the standards by which the quart and pint beer measures used in London are habitually adjusted, do not at present differ in a sensible degree from the standard proposed to be rendered general. We apprehend also that the slight excess of the new bushel above the common corn measure would be of the less importance, as the customary measures employed in different parts of Great Britain are almost universally larger than the legal Winchester bushel.

"Appendix (A). The standards kept at the Exchequer, for the adjustment both of CORN and BEER measures, are a bushel, a gallon, and a quart, dated 1601, and a pint, dated 1602, all marked with an E and a crown. They were examined by Sir George Clerk and Dr Wollaston, and the weight of Thames water which they held, at the temperature of 52°, was found as in the subjoined table. Now, since, according to Sir George Shuckburgh's experiments, a cubic inch of distilled water at 60° weighs $252\frac{1}{2}$ grains, the specific gravity of the water being to that of distilled water as 1·00060 to 1, and the apparent specific gravity of distilled water, in a vessel of brass at 52°, being to that of water at 62° as 1·00046 to 1, it follows that the apparent specific gravity of the water employed was 1·00106, and that an ounce avoirdupois corresponded to 1·731 cubic inches. Hence we obtain the contents of the measures in cubic inches, which are compared in the table with the more direct measurement of Mr Bird and Mr Harris, reported to the House of Commons in 1758.

	Oz. Avoir.	Cub. In.		Gallon.	Rep. 1758.
Pint	20·00	34·6	$(\times 8 =)$	276·9	34·8
Quart	40·35	69·8	$(\times 4 =)$	279·3	70·0
Gallon	156·25	270·4	$(=)$	270·4	271·0
Bushel	1229·85	2128·9	$(\times \frac{1}{8} =)$	266·1	2124·0

"The Exchequer standard WINE gallon is dated 1707, and was found to contain 133·4 ounces, answering to 230·9 cubic inches. An experiment of Dr Wollaston and Mr Carr, in 1814, gave 230·8, the mean being 230·85; while the measurement of 1758 made it 231·2. A duplicate of this measure, and of the same date, is kept at Guildhall.

"Dr Wollaston and Mr Carr examined also the three other WINE gallons at Guildhall. The oldest of these seems to be the same that was measured by Halley and Flamsteed in 1688, and was said to contain 224 cubic inches: its actual capacity is 224·4. The wine gallon of 1773, which is in daily use for adjusting other measures, was probably in the first instance a correct copy of the Exchequer gallon, but has been reduced by a bruise and by the wear of the brim to 230·0 cubic inches, having lost $\frac{4}{5}$ of a cubic inch, or $\frac{1}{300}$ of its whole capacity. The wine gallon of 1798 contains 230·8 cubic inches.

"The Excise WINE gallon was found by a similar experiment to contain 230·1 cubic inches, having partaken of the progressive deficiency of the Guildhall gallon, from which it was derived."

Second Report.—"We have examined, since our last Report, the relation of the best authenticated standards of length at present in existence, to the instruments employed for measuring the base on Hounslow Heath, and in the late trigonometrical operations; but we have very unexpectedly discovered that an error has been committed in the construction of some of those instruments. We are therefore obliged to recur to the originals which they were intended to represent, and we have found reason to prefer the parliamentary standard executed by Bird in 1760, which we had not before received, both as being laid down in the most accurate manner, and as the best agreeing with the most extensive comparisons which have been hitherto executed by various observers, and circulated throughout Europe; and, in particular, with the scale employed by the late Sir George Shuckburgh.

"We have therefore now to propose that this standard be considered as the foundation of all legal weights and measures, and that it be declared that the length of a pendulum vibrating seconds in a vacuum on the level of the sea, in London, is 39·13929 inches, and that of the French metre 39·37079 inches, the English standard being employed at 62° of Fahrenheit."

Third Report.—"The measurements which we have lately performed, upon the apparatus employed by the late Sir George Shuckburgh Evelyn, have enabled us to determine with sufficient precision the weight of a given bulk of water, with a view to the fixing the magnitude of the standard of weight, that of length being already determined by the experiments related in our former Reports; and we have found by the computations, which will be detailed in the Appendix, that the weight of a cubic inch of distilled water at 62° of Fahrenheit is 252·724 grains of the parliamentary standard pound of 1758, supposing it to be weighed in a vacuum."

Appendix.—The commissioners having been furnished, by the kindness of the Honourable C. C. C. Jenkinson, with the apparatus employed by the late Sir George Shuckburgh Evelyn in the determination of the magnitude of the standard weights, and there being some doubt of the perfect accuracy of his method of measuring the capacity of the bodies employed, it was judged necessary to repeat that measurement with greater precautions; and the results of Captain Kater's experiments have afforded some slight corrections of the capacities in question.

"The sides of Sir George Shuckburgh's cube were found by Captain Kater equal to 4·98911, 4·98934, and 4·98935 inches, the diameter of the cylinder 3·99713, and its length 5·99600 inches; and the diameter of the sphere 6·00759 inches. Hence the content of the cube appears to be 124·1969 inches; that of the cylinder 75·2398; and that of the sphere 113·5264 inches of Bird's parliamentary standard of 1760, recommended in the last Report of the commissioners, or of the standard made by Troughton for Sir George Shuckburgh.

"The difference of the weight of the cube in the air at 62°, with the barometer at 29·0, and in water at 60·2°, was 31381·79 grains; and adding to this the weight of an equal bulk of the air at 62°, which is $\frac{1}{834}\cdot\frac{29}{30}$ of that of the water, or 36·26 grains, and subtracting from it $\frac{1}{8\cdot5}$ of this, or 4·26 grains, the buoyancy of the brass weights, we obtain 31413·79 grains for the weight of the cube of water in a vacuum at 60·5. Now this cube is less than the supposed measure, at the standard temperature of 62°, in the ratio of 1 to 1·000567, on account of the contraction of the brass, and the water is denser than at the standard temperature, according to Mr Gilpin's experiments, in the ratio of ·99998 to ·99981, or of 1·00017 to 1; the whole correction for the difference of 1·8° being ·0001133, or 3·55 grains, making 31410·24 for the weight of the cube of water in a vacuum at 62°; which, divided by 124·1969, gives 252,907 for the weight of a cubic inch, in Sir George Shuckburgh's grains.

"In the same manner, we obtain for the cylinder, which was weighed in air under the same circumstances, and in water at 60·5°, the difference being 19006·83 grains, the correction $\frac{1}{834}\cdot\frac{29}{30}\cdot\frac{7\cdot5}{8\cdot5}$ for the effect of buoyancy, amounting to 19·43 grains; and for the difference of temperature of the water and brass conjointly, the densities being ·999955 and ·999810, the correction ·000145 — ·000047 = ·000095, or 1·80 grains, leaving + 17·63 grains for the whole correction of the weight, as reduced to a vacuum at 62°, and making it 19024·46, which, divided by 75·2398, the content of the cylinder, affords us 252·851 for the cubic inch in a vacuum at 62°.

"The sphere was weighed in air at 67°, the barometer standing at 29·74; the correction for the buoyancy is here $\frac{7\cdot5}{8\cdot5}\cdot\frac{29\cdot74}{30}\cdot\frac{1}{843}$, or, for 28673·51 grains, 29·72; while the temperature of 66° requires, for the difference between the expansion of brass and water, the addition of ·00042 — ·000126, or ·000294 of the whole, that is, + 8·43 grains, making the whole correction 38·15, and the weight in a vacuum 28711·66; which, divided by 113·5264, gives us 252·907 for the cubic inch in a vacuum.

'The mean of these three measures is 252·888, giving for the three errors +·019, —·037, and +·019; and this mean, reduced to the parliamentary standard, makes 252·722 grains for the cubic inch of distilled water at 62° weighed in a vacuum, or 252·456 in air, under the common circumstances of the atmosphere, when weights of brass are employed. In a vacuum, at the maximum of density, that is, at 39°, the weight of a true cubic inch will be 253 grains, and of a cubic decimetre 15,440.[1] The proposed imperial gallon of ten pounds, or 70,000 grains of water, will contain very nearly 277·3 cubic inches, under common circumstances."

In conformity with these Reports, a bill was brought into the House of Commons in 1822 by Sir George Clerk, and again, with a few alterations, in 1823, which appears to have been drawn up with great care and judgment, and which comprehends a statement of the true ground of the proposed measures, and of the determinations which are intended for their bases.[2]

'Whereas notwithstanding it is provided by the Great Charter, that there shall be but one measure and one weight throughout the realm, and by the Treaty of Union between England and Scotland, that the same weights and measures should be used throughout Great Britain as were then established in England, yet different weights and measures, some larger and some less, are still in use in various places throughout the united kingdom of Great Britain and Ireland, and the true measure of the present standards is not verily known, which is the cause of great confusion and of manifest frauds: Be it therefore enacted, That the straight line or distance between the centre of the two points in the gold studs in the straight brass rod now in the custody of the clerk of the House of Commons, whereon the words and figures 'Standard Yard, 1760,' are engraved, shall be, and the same is hereby declared to be, the original and genuine standard of that measure of length or linear extension called a yard; and that the same straight line or distance between the centres of the said two points in the said gold studs in the said brass rod, the brass being at the temperature of sixty-two degrees by Fahrenheit's thermometer, shall be and is hereby denominated the 'Imperial Standard Yard,' and shall be, and is hereby declared to be, the unit or only standard measure of extension wherefrom or whereby all other measures of extension whatsoever, whether the same be linear, superficial, or solid, shall be derived, computed, and ascertained; and that all measures of length shall be taken in parts or multiples, or certain proportions of the said standard yard; and that one third part of the said standard yard shall be a foot, and the twelfth part of such foot shall be an inch; and that the pole or perch shall contain five such yards and a half, the furlong 220 such yards, and the mile 1760 such yards....

" And whereas it is expedient that the said standard yard, if lost, destroyed, defaced, or otherwise injured, should be restored of the same length by reference to some invariable natural standard; and whereas it has been ascertained, by the commissioners appointed by his majesty to inquire into the subject of weights and measures, that the said yard hereby declared to be the imperial standard yard, when compared with a pendulum vibrating seconds of mean time in the latitude of London, in a vacuum at the level of the sea,...is in the proportion of thirty-six inches to 39·1393; Be it therefore enacted and declared, That if at any time hereafter the said imperial standard yard shall be lost, or shall be in any manner destroyed, defaced, or otherwise injured, it shall and may be restored by making, under the direction of the Lord High Treasurer...for the time being, a new standard yard, bearing the same proportion to such pendulum as aforesaid, as the said imperial standard yard bears to such pendulum.

" And whereas the commissioners appointed by his majesty to inquire into the subject of weights and measures have recommended that the standard brass weight of two pounds troy weight, made in the year 1758, and now in the custody of the clerk of the House of Commons, shall be considered as authentic; Be it enacted, That a brass weight equal to one half of the said brass weight of two pounds, gravitating in air (the barometer being at thirty inches, and the thermometer being at 62° by Fahrenheit's scale), 1822 [1823, be it further enacted, That the standard brass weight of one pound troy weight, made in the year 1758, now in the custody of the clerk of the House of Commons], shall be, and the same is hereby declared to be, the original and genuine standard measure of weight; and that such brass weight...shall be and is hereby denominated the Imperial Standard Troy Pound, and shall be, and the same is hereby declared to be, the unit or only standard measure of weight, from which all other weights shall be derived, computed, and ascertained; and that $\frac{1}{12}$th of the said troy pound shall be an ounce, and that $\frac{1}{20}$th of such ounce shall be a pennyweight, and that $\frac{1}{24}$th of such pennyweight shall be a grain, so that 5760 such grains shall be a troy pound; and that 7000 such grains shall be, and are hereby declared to be, a pound avoirdupois; and that $\frac{1}{16}$th of the said pound avoirdupois shall be an ounce avoirdupois; and that $\frac{1}{16}$th of such ounce shall be a dram.

---

[1] It appears, however, from an official Report obligingly communicated to us by Dr Kelly, that the actual standard chiliogramme has been found to contain only 15,433 English grains.

[2] This act, of which only partial quotations of the principal provisions are given here, is nearly the same with the 5th Geo. IV. cap. 74, which was passed 17th June 1824, to come into operation 1st May 1825, but postponed by 6 Geo. IV. cap. 12, to 1st January 1826. Most of its provisions are still in force, and indeed were only rendered compulsory by 5 and 6 Will. IV. cap 63, from 1st January 1836; the principal parts repealed by the latter statute being the use of heaped measure, and of local and customary weights and measures.]

"And whereas it is expedient that the said standard troy pound, if lost, destroyed, defaced, or otherwise injured, should be restored of the same weight, by reference to some invariable natural standard; and whereas it has been ascertained by the commissioners appointed by his majesty to inquire into the subject of weights and measures, that a cubic inch of distilled water in a vacuum, weighed by brass weights, also in a vacuum, at the temperature of 62° of Fahrenheit's thermometer, is equal to 252·72, 1822 [1823, 252·724] grains, of which, as aforesaid, the imperial standard troy pound contains 5760; Be it therefore enacted, That if at any time hereafter the said imperial standard troy pound shall be lost...it shall and may be restored.... by making, under the directions of the Lord High Treasurer, ...a new standard,"...determined according to this proportion.

"And be it further enacted, That the standard measure of capacity, as well for liquids as for dry goods, shall be the gallon, containing ten pounds avoirdupois weight of distilled water, weighed in air, at the temperature of 62° of Fahrenheit's thermometer, the barometer being at thirty inches; and that a measure shall be forthwith made of brass, of such contents as aforesaid,...and such brass measure shall be, and is hereby declared to be, the imperial standard gallon, and shall be, and is hereby declared to be, the unit and only standard measure of capacity, from which all other measures of capacity to be used, as well for wine, beer, ale, spirits, and all sorts of liquids, as for dry goods, shall be derived, computed, and ascertained; and that all measures shall be taken in parts or multiples, or certain proportions, of the said imperial standard gallon; and that the quart shall be the fourth part of such standard gallon, and the pint shall be one eighth of such standard gallon; and that two such gallons shall be a peck, and eight such gallons shall be a bushel, and eight such bushels a quarter of corn or other dry goods.

"And be it further enacted, That the standard measure of capacity for coals, culm, lime, fish, potatoes, or fruit, and all other goods and things commonly sold by heaped measure, shall be the aforesaid bushel, containing eighty pounds avoirdupois of water as aforesaid, the same being made round, with a plain and even bottom, and being 19½ inches from outside to outside of such standard measure as aforesaid.[1]

"Provided always, and be it enacted, That in all cases of dispute respecting the correctness of any measure of capacity, arising in a place where recourse cannot conveniently be had to any of the aforesaid verified copies or models of the standard measures of capacity, it shall and may be lawful to and for any justice of the peace, or magistrate, having jurisdiction in such place, to ascertain the content of such measure of capacity by direct reference to the weight of pure or rain water which such measure is capable of containing; ten pounds avoirdupois weight of such water, at the temperature of 62° by Fahrenheit's thermometer, being the standard gallon ascertained by this act, the same being in bulk equal to 277·276, 1822 [1823, 277·274] cubic inches, and so in proportion for all parts or multiples of a gallon."

The slight discordance between the numbers of the two successive years depends merely on the adoption of a standard troy pound, better authenticated than the two-pound weight particularly employed by Sir George Shuckburgh, which was finally preferred, both as representing a unit, and as being more simple in its form than the two-pound weight.

[1] [Although the act 5 and 6 Will. IV., cap. 63, has abolished the use of heaped measure, it enacts that this form and size of bushel shall still be used for such goods sold by measure as are neither liquid nor admit of being stricken. But it is obvious, that when there is to be no heap, it is not the outside diameter, but the inside one, that ought to have been fixed for such goods; whereas the statutes have left this so indeterminate, that it may vary an inch or more according to the thickness of the materials.]

(L. L.)

The preceding part of this article was furnished by the late Dr Thomas Young, for the Supplement to the former editions, in such a form as not to supersede any thing previously given on the same subject in the body of the work; so that, both for this reason, and on account of the changes which have taken place since Dr Young wrote, some additions are required. Indeed, excepting the comparative table, this supplementary article was almost entirely confined to the then only proposed equalization of the very different weights and measures employed in different parts of the British empire, but on which four successive legislative enactments have since taken place. These are, 5 Geo. IV. c. 74, 6 Geo. IV. c. 12, 4 and 5 Will. IV. c. 49, and 5 and 6 Will. IV. c. 63. The first two of these statutes were exceedingly inert, being little better than mere recommendations or abstract speculations, from the circumstance that every one was still allowed to use whatever weight or measure his fancy, habits, or interest led him to prefer. The third has been repealed or superseded by the fourth; and the latter, which was passed in 1835, besides abolishing heaped measures, declares all bargains or transactions to be illegal, or null and void, which are made by any other weights or measures than the imperial. But although this law, which came into operation 1st January 18[illegible], has certainly placed the matter on a very different footing from what it was before, the equalization is so far from being yet complete, that two, and in some respects three, different sorts of weights are very needlessly allowed, which tends to create confusion, and affords opportunity for fraudulent transactions. This, it seems, was done principally in compliance with the wish of the College of Physicians, who had long been in the habit of using the troy weight in their prescriptions. It seems quite clear, that if any class of the community was to be so indulged, it should have been such as were ready to plead being so far behind the rest that they could not reduce the troy to avoirdupois. There is however no good reason why physicians' prescriptions should in this respect always continue antiquated, and lagging behind every thing else, any more than there is that physicians should always continue to use unclassical Latin instead of their mother tongue.

The parliamentary commissioners on weights and measures think there is reason to believe that the word Troy has no reference to any town in France, but rather to the monkish name of *Troy Novant* given to London, as founded on the legend of Brute. Troy weight would thus mean London weight. But some would derive Troy or Troyes, from *trois* (three), alleging it has reference to the three principal divisions of penny, shilling, and pound, or penny, ounce, and pound, used in money weight. The commissioners, with great probability, suppose the avoirdupois weight, by which heavy and bulky goods have very generally been weighed for a long time past throughout this country, to be derived from *avoirs* (*averia*), the ancient name for goods and chattels, and *poids*, weight.

The act 5 and 6 Will. IV. cap. 63, contains several important provisions, the substance of which we shall now endeavour to state briefly. Weights and measures verified and stamped at the exchequer as copies of the imperial standards shall be taken to be legal weights and measures, to be used for comparison, although not similar in shape to those required under the provisions of former acts, except, as will be afterwards explained, those measures used for such articles as were formerly heaped, and now are neither weighed nor stricken; and the comptroller-general, or other duly authorized officer of the exchequer, may compare and verify, and stamp as correct standards, any weights and measures which respectively correspond in weight, length, and capacity, with the standards, or parts, or multiples thereof, deposited in the exchequer, under the 5th Geo. IV. cap. 74, although, with the exception above noticed, such weights and measures may not be models or copies in shape or form of the standards so deposited.

All copies of the imperial standard weights and measures which have become defective, or have been mended, in consequence of wear or accident, shall forthwith be sent to the exchequer, for the purpose of being again compared and verified, and shall be stamped as re-verified copies of such standards, provided the officer appointed for such verification deem them fit for the purposes of standards, and every new comparison and verification shall be indorsed upon the original indenture of verification; and such weights and measures shall be stamped upon fees of verification only, unless they have been found incorrect; for in that case an extra charge is to be made for adjusting them.

The Winchester bushel, the Scotish ell, and all local or customary measures, are now abolished; and every person who shall sell by any other than one of the imperial measures, or some multiple or aliquot part thereof, shall be liable to a penalty not exceeding 40s. for every such sale; but nothing herein shall prevent the sale of any articles in any vessel, where such vessel is not represented as containing any amount of imperial measure, or of any fixed local or customary measure formerly in use.

The use of heaped measure is now abolished, and all bargains, sales, and contracts by heaped measure are null and void, under a penalty not exceeding 40s. for every such sale.

Some articles formerly sold by heaped measure do not admit of being stricken, and cannot conveniently be sold by weight. It is enacted that all such articles may in future be sold by the imperial bushel, but as having its form defined by the act 5 Geo. IV. cap. 74, for the sale of heaped measure, the diameter being nineteen and a half inches outside, or any multiple or aliquot part thereof, also defined by the same act, such being filled in all its parts as nearly even with the brim as the size and shape of the articles will admit (see foot-note, p. 846); but nothing herein shall prevent the sale by weight of any article formerly sold by heaped measure. All coals, slack, culm, and cannel of every description, shall be sold by weight and not by measure, under a penalty of 40s. for every sale.

All articles sold by weight shall be sold by avoirdupois weight, except gold, silver, platina, diamonds, or other precious stones, which may be sold by troy weight; and drugs, which, when sold by retail, may be sold by apothecaries' weight. The weight denominated a stone shall in all cases consist of fourteen standard pounds avoirdupois; the hundredweight of eight such stones, or 112 lbs.; and the ton of twenty such hundredweights; but nothing herein shall prevent any bargain, sale, or contract being made by any multiple or aliquot part of the pound weight.

All weights of one pound avoirdupois, or more, shall have the number of pounds contained in them stamped or cast on the top or side, in legible figures or letters; and all measures of capacity shall have their contents stamped or marked on the outside in legible figures and letters.

The stamping of weights entirely composed of lead or pewter, or of any mixture thereof, is prohibited; but nothing herein shall prevent the use of lead or pewter, or any mixture thereof, in the manufacture of weights, if these are wholly and substantially cased with brass, copper, or iron, and legibly stamped or marked "cased;" or shall prevent the insertion of such a plug of lead or pewter into the weights as shall be *bona fide* necessary for adjusting them, and receiving the impression of the stamp. Nothing herein shall require any single weight above fifty-six lbs. to be inspected or stamped, nor any wooden or wicker measure used in the sale of lime, or other articles of the like nature; or any glass or earthenware jug or drinking cup, though represented as containing the amount of any imperial measure, or of any multiple thereof; but any person buying by any vessel represented as containing the amount of any imperial measure, or of any multiple thereof, is authorized to require the contents of such vessel to be ascertained by comparison with a stamped measure, to be provided by the person using such wooden or wicker measure, glass jug, or drinking cup, and if such comparison be refused, or the measure be found deficient, the person using the same shall be liable to the penalties imposed on those using unjust weights or measures.

The following is a tabular view of the weights and measures, according to the present state of the law, throughout the British empire. In some of the colonies, however, and particularly in India, a variety of other weights and measures besides is still in use, as will be noticed in the sequel. It is only necessary to observe, that all the quantities in the same horizontal line of the same table are equal to each other.

Troy Weight.

Grains.	Dwts.	Oz.	Lb.
24	1	...	...
480	20	1	...
5760	240	12	1

Apothecaries' Weight.

Troy Grains.	Scruples.	Drams.	Oz.	Lb.
20	1	...	...	...
60	3	1	...	...
480	24	8	1	...
5760	288	96	12	1

In these two weights the grain, ounce, and pound are the same. The troy is used for the precious metals and for jewels, as also in trying the strength of spirituous liquors, and for comparing different weights with each other. Four grains troy make a carat. But this term when applied to gold denotes its degree of fineness. Thus, the weight of any quantity or compound of that metal being supposed to be divided into 24 equal parts, if the mass be pure gold, it is said to be 24 carats fine. If it consist of 23 parts of pure gold and 1 of alloy, it is said to be 23 carats fine, and so on. Diamonds and pearls are also weighed by carats of 4 grains, but 5 diamond grains are only equal to 4 troy grains. This sort of weight is not very different all over the globe. There are 150 diamond carats in the troy ounce. Apothecaries' weight is chiefly used for medical prescriptions; but drugs are mostly bought and sold, especially in wholesale, by avoirdupois weight.

Avoirdupois or Commercial Weight.

Troy Grains.	Drams.	Oz.	Lbs.	Stones.	Qrs.	Cwts.	Ton.
437·5	16	1	...	...	...	...	...
7000	256	16	1	...	...	...	...
98000	3584	224	14	1	...	...	...
196000	7168	448	28	2	1	...	...
784000	28672	1792	112	8	4	1	...
15680000	573440	35840	2240	160	80	20	1

The above lb. of 7000 troy grains was formerly subdivided into 7680 avoirdupois grains, 10 of which made a scruple, 30 a dram, and 480 an ounce. The troy pound is less than the avoirdupois in the proportion of 144 to 175, or of 14 to 17 nearly; but the troy ounce is greater than the avoirdupois in the proportion of 192 to 175, or of 79 to 72 nearly.

Measures of Length.

Inches.	Links.	Feet.	Yards.	Pole or Perch.	Chains.	Furlongs.	Mile.
7·92	1	...	...	...	...	...	...
12	1·515	1	...	...	...	...	...
36	4·545	3	1	...	...	...	...

6272640	100000	43560	4840	160	10	4	1

In the superficial measurement of stone, brick, or slate work, 36 square yards are termed a rood, and 100 square feet of flooring a square. There are 1728 cubic inches in the cubic foot, and 27 cubic feet in the cubic yard; 40 cubic feet of rough, or 50 of hewn timber, make a load or ton. A cubic yard of earth is called a load.

Imperial Liquid and Dry Measure, deduced from the Standard Gallon containing 10 lbs. avoirdupois of distilled water at the temperature of 62° Fahrenheit, and barometer 30 inches.

Pounds of Water.	Cubic Inches.	Gills.	Pints.	Quarts.	Pottles.	Gallons.	Pecks.	Bushels.	Coombs.	Quarter.
1·25	34·659	4	1		...	...	...	...	...	...

80	2218·191	256	64	32	16	8	4	1	...	...
320	8872·763	1024	256	128	64	32	16	4	1	...
640	17745·526	2048	512	256	128	64	32	8	2	1

This measure came first into operation 1st January 1826, but has only been compulsory as the sole legal measure of capacity since 1st January 1836. The peck, bushel, coomb, and quarter are dry measures only.

In beer measure, the barrel consists of 36 gallons = 4 firkins, and the hogshead contains 1½ barrel or 54 gallons. The anker, tierce, hogshead, puncheon, pipe, butt, and tun, used for wine and spirits, are so vague and variable in their contents, that they are to be considered rather as the names of the casks than as expressing any fixed or definite measures. However, such vessels are usually gauged, and have their contents, whatever they may be, marked on them. But for a great variety of local and customary weights, measures, and packages of a less general nature, we beg to refer to the Second Report of the Parliamentary Commissioners on Weights and Measures, to Buchanan's Treatise on the same subject, and to Waterston's Manual of Commerce.

In the old English wine measure, 32 gills = 8 pints = 4 quarts = 1 gallon = ·83311 imperial gallon; so that 6 old wine gallons were very nearly equal to 5 imperial.

In the old English ale measure, 8 pints = 4 quarts = 1 gallon = 1·01704 imperial gallon.

All the denominations of the old English or Winchester dry measure were the same as those of the imperial, but each of the former was less than the latter in the proportion of 32 to 33 nearly, or, more accurately, of ·969447 to 1. Wherefore, each of the Winchester measures will be reduced to imperial by multiplying it by ·969447.

n Scotish troyes, or Dutch weight (which, under the name of nch troys, was, by the acts of the Scotish parliament of 1617 1618, declared to be the only legal weight for Scotland, and standard of which was committed to the keeping of the borough Lanark), 4096 drops = 256 ounces = 16 lbs. = 1 stone = 391885 lbs. avoird., according to the verdict of the Edinburgh (4th February 1826), from weighing the original Lanark stone, in the custody of the Dean of Guild of Edinburgh. But in ctice the Dutch stone was more generally reckoned, and probly was adjusted to, 17·5 lbs. avoirdupois; or 4 Dutch stones e = 5 imperial stones of 14 lbs. each. In this way although utch stones were said to form the standard Scotish meal boll, as commonly reckoned to be just ten imperial stones, or 140 avoirdupois.

he tron weight, although condemned to be utterly abolished he statutes above cited, continued in use, and varied through- Scotland from 21 to 28 ounces avoirdupois to the pound, which Edinburgh contained 22 of these ounces. It was generally l for butter, cheese, and in many places for butcher-meat, , &c. Its multiples and subdivisions were similar to those of Dutch. A stone of 16 lbs. avoirdupois, called customary weight, also to be met with in many places both in England and Scot- l. Nay, in some places this went by the name of Dutch weight, le the Dutch, again, was called Edinburgh weight.

The Scotish ell was = 37·0598 imperial inches; and 1920 ells = 320 falls = 8 furlongs = 1 mile = 1·123024 imperial mile. The Scotish chain for land measure, like the imperial, consisted of 100 links, and though often reckoned to have been just 74 imperial feet, was more correctly = 24 ells = 74·1196 feet; and 5760 square ells = 160 falls = 10 square chains = 4 roods = 1 acre = 1·261183 imperial acre. Scotish acres will therefore be reduced to imperial, by multiplying them by 1·261183. Twenty-three Scotish acres made about 29 imperial, or, more nearly, 134 Scotish = 169 imperial.

In the old Scotish liquid measure, 128 gills = 32 mutchkins = 16 chopins = 8 pints = 1 gallon = 3·00651 imperial gallons.

Although several of the old Scotish dry measures were very different in different districts, most of them were similarly subdivided, having 64 lippies or forpets = 16 pecks = 4 firlots = 1 boll. In some of them, however, the bolls, especially where they were large, had very different sorts of subdivisions. But for an account of these, we must, for brevity's sake, refer to Mr Buchanan's very complete treatise on the subject. The proportion of an entire boll of each to the imperial measures, as determined by the verdicts of the juries in the different counties, in terms of the act 5 Geo. IV., cap. 74, will be seen from the following table, which may often be of use in interpreting contracts or leases based on the old measures.

ble shewing how many Imperial Bushels, Pecks, Gallons, and Decimals, are contained in one Boll of each of the Old Scotish Local Measures for Barley, Oats, Wheat, &c.

One Boll.	Barley, Oats, &c.			Wheat, &c.

he old Linlithgow corn measures (which by acts of the Sco- parliament of 1617 and 1618 were declared to be the only le- measures for Scotland, the wheat firlot heaped having till then n used for barley and oats, when an equivalent separate firlot for se was first introduced) were also, previously to the imperial asures, used in the counties of Dumfries, Edinburgh, Hadding- , Lanark, Peebles, Perth, and Wigton. They differed little n the one of the two bolls used in several other counties, es- ially that for wheat, as will be seen from the table. The term is still retained, six imperial bushels being generally reckoned he boll of barley or oats, and four such bushels to the boll of eat, &c.

n the old Irish measures, 11 miles were equal to 14 imperial es, and 121 acres made 196 imperial acres. Twenty imperial nes were reckoned a barrel of wheat, peas, beans, or rye; 16 a rel of barley, bere, or rapeseed; 14 a barrel of oats; and 12 arrel of malt. To the Winchester quarter were reckoned 41 nes of wheat or rye, 24 of barley, 22 of oats, and 20 of malt. the old Irish gallons, 200 made 157 imperial gallons.

The troy grain is equal to ·064792 French gramme, the troy lb. ·373202 kilogramme; the avoirdupois lb. = ·453544 kilogramme. e British yard = ·914379 metre; the mile = 1·609305 kilo- tre; the acre = ·404667 hectare; the gallon = 4·543389 litres; bushel = ·363471 hectolitre; and the quarter = 2·907769 tolitres. The reduction of French to British is subsequently en.

n the following general comparison of the principal foreign ghts and measures with the British, instead of the term *im- al*, which alone must be nearly unintelligible to foreigners, and eed has become next to superfluous after every other standard ceased to be legal in this country, we shall use the term *Bri-* to denote such of the standards as are uniform, and *troy* and *rdupois* to express the two different kinds of weights respec- ly.

lgiers.—Since the French conquest, the metrical system and *système usuel* of France are generally used by European merchants. The metalli of oil = 37·375 lbs. avoirdupois; and 100 rotoli = 119 lbs. avoirdupois. The metical = 73 troy grains. The Turkish pic used for cloth = 24·5 British inches; but the Moorish pic is only three fourths as long; and 16 tarries = 1 caffise = 8·75 British bushels.

Argentine Republic.—Same as in Spain.

Arabia.—The weights and measures of Egypt are much used where the sway of Mehemet Ali has extended. Besides these, 200 rattles = 100 maunds = 10 frazils = 1 bahar = 222·5 lbs. avoird.

Austria.—Of the weights, 32 loths = 16 oz. = 4 quarters = 1 commercial lb.; and 100 lbs. = 1 centner = 123·56 lbs. avoird. Also 20 lbs. = 1 stone. The Vienna mark of 4333 grains troy is used for gold and silver. Five such marks make nearly 6 marks of Cologne. Of Vienna measures, 6 feet make one klafter or fathom = 6·23 Brit. feet; 1 ell = 30·6 Brit. inches; 4000 klaftern = 1 posting mile = 4·71 Brit. miles; and the joch = 6889 Brit. sq. yds. Also 70 kopfen = 40 maasses = 4 viertels = 112·46 Brit. gall. Of wine, 32 eimers = 1 fuder; and 30 eimers = 1 dreyling. Eight achtels of corn = 4 viertels = 1 metzen = 1·69 Brit. bushel, and 30 metzen make 1 muth. At Trieste, the woollen ell = 26·6 Brit. inches; the silk ell = 25·22 Brit. inches; the eimer or orna of wine = 12·45 Brit. gallons; the barile = 144·5 Brit. gall. The orna of oil = 14·17 Brit. gall.; and the stajo of corn = 2·272 Brit. bushels. But sometimes the weights and measures of Venice, about to be described, are used here.

In public and official matters, the decimal system of France was in effect adopted, though under a different nomenclature, in the Austrian states of Italy in 1804. Thus 10,000 grani = 1000 denari = 100 grossi = 10 oncie = 1 libra nouva = 1 kilogramme = 2·2086 lbs. avoird.; 1000 atomi = 100 diti = 10 palmi = 1 metre = 39·3708 Brit. inches; and 1000 copi = 100 liti = 10 mine = 1 soma = 1 hectolitre = 2·7512 Brit. bushels. The decimal system is principally used in public affairs, the old weights and measures being in more general use for ordinary trade. In Milan, the mark = 3627 grains troy; the lb. peso grosso = 2·3343 lbs. sottile = 1·6818 lb. avoird.; and the oil rubio = 47·5 same lbs. The wine brenta = 15·72 Brit. gall.; the corn stajo = 2·008 Brit. pecks. In Venice, the lb. peso grosso = 1·0519 lb. avoird.; the lb. sottile = ·6643 lb. avoird.; and the mark = 3681·5 grs. troy. The woollen braccio = 26·6 Brit. inches; the silk braccio = 24·8 same inches; the wine secchо = 2·376 Brit. gall.; the oil miro = 3·354 Brit. gall.; and the corn stajo = 2·20 Brit. bushels.

Australia.—Same as in Britain.

Baden.—One hundred lbs. = 10 stones = 1 centner = 50 kilogrammes = 110·2429 lbs. avoird. There are 2 feet in the new aune = 6 decimetres = 23·62 Brit. inches. The morgen of land = 36 French ares = ·8896 Brit. acre. Also 150 litres = 1 ohm = 33·015 Brit. gallons; and 20 malters of corn = 1 last = 30 hectolitres = 10·32 Brit. quarters.

Bavaria.—The centner or quintal = 100 lbs. = 5 stones = 56 kilogrammes = 123·5 lbs. avoird. Gold and silver are weighed by the Cologne mark of 3608 troy grains. The ell = 32·8 British inches; the eimer of wine = 60 maas = 8·12 Brit. gallons; and 12 viertels = 6 metzen = 1 scheffel = 9·98 Brit. bushels. In the old system of Augsburg, 100 lbs. heavy weight = 108·3 lbs. avoird.; and 100 lbs. light weight = 104·23 lbs. avoird. The mark = 3643 troy grains, and is divided into 16 loths = 64 quintins.

Belgium.—In 1820, this country and Holland being under one government, the French metrical system was introduced into both, but with the old Dutch nomenclature, as follows. Ten korrels = 1 wigtje = 1 gramme = 15·434 troy grains; and 1000 wigtjes = 100 loods = 10 ons = 1 pond = 1 kilogramme = 2·20486 lbs. avoird. The apothecaries' new pound is divided into 12 oz. = 96 drams = 288 scruples = 5760 grains = 5787 grains troy. Ten palms = 1 elle = 1 metre = 39·3708 Brit. inches; also 1 mijle = 1 kilometre = 1093·633 Brit. yds.; and 100 square elles = 10 sq. roedes = 1 sq. bunder = 1 are = 119·6033 Brit. sq. yds. The cubic elle = 1 stère = 1·30802 Brit. cubic yd.; and 100 vingerhoeds = 10 maatjes = 1 kan = 1 litre; and 100 kans = 1 vat liquid measure = 1 hectolitre = 22·009 Brit. gallons. Also 100 kops = 10 schepels = 1 mudde or zak dry measure = 1 hectolitre = ·3439 British quarter.

Of the old systems still partially in use in many places, the Brabant lb. = 1·0335 lb. avoird.; the ell = 27·58 Brit. inches; and the league = 6076 Brit. yds. The aam of 50 stoops = 32·4 Brit. gallons; the velte = 4·1 Brit. gall.; and 37·5 viertels = 1 last = 82 Brit. bushels. The Antwerp silk ell = 27·32 Brit. inches, and the woollen ell = 26·97 of same inches.

Brazil.—In general the same as in Portugal. But in trade the following are also in use. The lb., of which 99 = 100 lbs. avoird. Five varas = 6 British yds.; and 4 covados = 3 Brit. yds. The medida of Rio Janeiro, of which 100 = 61·1 Brit. galls.; and 12 alqueires = 12·86 Brit. bushels. The canada of Bahia = 1·667 Brit. gall.; and 7 alqueires = 5·817 Brit. bushels. The alqueire of Maranham = 1·11 Brit. bushel.

Bremen.—The lb. consists of 16 ounces, and the lispond of 14 such lbs., of which 116 = 1 centner = 127·44 lbs. avoird. Hence 10 lbs. of Bremen make nearly 11 avoird. The Cologne mark is used for gold and silver. The ell of 2 feet = 22·76 Brit. inches, and 180 quarts = 45 stubchens = 20 viertels = 1 ahm = 31·5 Brit. gallons. Six ahms = 1 fuder of Rhenish wine, and 44 stubchens = 1 ahm of French wine. In corn measure, 640 spinets = 160 viertels = 40 scheffels = 4 quarts = 1 last = 9·77 British quarters.

Brunswick.—The centner consists of 114 lbs., and 100 lbs. = 103 lbs. avoird. Two feet = 1 ell = 22·46 Brit. inches. Forty stubgens = 1 wine ahm = 32·28 Brit. gall. Forty himtens of corn = 4 scheffels = 1 wispel = 34·2 Brit. bushels.

Buenos Ayres.—The same as in Spain.

Burman Empire.—Most commodities are bought and sold by weight. Of rice, 64 sales = 16 vis = 4 saits = 1 ten or basket = 57·36 lbs. avoird., but generally reckoned at half a cwt. Other grain, pulse, fruit, salt, and also lime, are measured. One hundred kaits = 1 vis or paiktha = 3·59 lbs. avoird.; and 150 vis = 1 candy = 500 lbs. avoird.

Canada.—The same as in Britain, except that the old English measures of capacity are still partially used, as also the old French minot = 1·0556 Brit. bushel; or 45 minots = 49 Winchester bushels, though commonly reckoned at 50.

Canary Isles.—The same as in Spain; but in the corn trade, 4·5 fanegas of wheat or barley, and 3·167 of maize or Indian corn, are reckoned to the Winchester quarter.

Candia.—The oke = 2·75 lbs. avoird., and the quintal = 126 of same lbs. The ell or pik = 25·11 Brit. inches; the dennum measure of surface = 40 sq. yds. The mistach is a variable measure of wine from 3 to 5 Brit. gall.; that of oil is more nearly 3 gall. Corn is measured by the carga = 4·19 Brit. bushels.

Cape of Good Hope.—The Dutch standards, which were formerly used here, have now in a great measure been superseded by the British. One hundred Dutch lbs. = 108·923 lbs. avoird. The muid of wheat weighs about 110 lbs. Dutch, or fully 119·6 avoird.; and 100 Dutch ells = 75·47 Brit. yds.; also 100 morgen = 201 Brit. acres. In corn measure, 4 schepels = 1 mudde or muid = 3·06 Brit. bushels; and 4 ahms = 1 leaguer = 126·63 British gallons.

Ceylon.—For foreign commodities, the British weights are generally employed. The candy or bahar = 500 lbs. avoird., and the garce = 82 cwts. 2 qrs. 16·5 lbs. The bale of cinnamon = 92¼ lbs. avoird. Of the native measures, 192 seers = 8 parrahs = 1 amomam = 5·57 Brit. bushels; the last of corn = 6·54 Brit. quarters; and 300 canadas = 75 welts = 1 leaguer in the retail of arrack = 125 Brit. gall.; but in wholesale, the leaguer of arrack = 80 welts. Besides the British standards of length and surface, 40 coornies in the land measure of Kandi = 4 peylas = 1 amc mam = 2·7344 Brit. acres.

Chili.—In general the same as in Spain. But 24 lbs. of Chi = 25 of Spain = 25·36 lbs. avoird., and 27 varas = 25 British yards.

China.—Liquids and grain are bought and sold by weight, of which 1000 cash = 100 candereens = 10 mace = 1 tael = 583·33 grains troy; and 1600 taels = 100 catties = 1 pecul = 133·33 lbs. avoird.; so that 3 peculs = 400 lbs., 84 catties = 1 cwt., and 12 taels = 1 lb. But in money weight, the tael is about 3·5 grains less. Of the measures, 10 punts = 1 covid = 14·625 Brit. inches; or 32 covids = 13 Brit. yds. The li = 180 fathoms = 632 Brit. yds., and 200 lis = 1 degree of the meridian.

Corsica.—In general the same as in France. At Bastia, the stajo of corn = 4·125 Brit. bushels, and the barile of wine = 30·8 Brit. gallons.

Cuba.—Generally the same as in Spain. The following are also used in trade: 100 lbs. = 4 arrobas = 1 quintal = 101·75 lbs. avoird. The vara = 33·333 Brit. inches; the fanega = 2·9 Brit. bushels; the arroba for wine or spirits = 3·42 Brit. gallons.

Denmark.—Of the weights, 320 lbs. = 20 lisponds = 1 shippond = 3·143 British cwts.; and 100 lbs. = 1 centner = 110·25 lbs. avoird. Gold and silver are weighed by the Copenhagen mark of 8 ounces = 3633 grains troy. Two Rhinland feet = 1 ell = 24·75 Brit. inches; and 2400 ruthes = 1 mile = 4·684 Brit. miles. Eight pots = 4 kans = 1 viertel = 1·7 Brit. gall.; 30 viertels = 1 hogshead = 51 Brit. gall.; 4 ankers = 1 ahm = 33·25 Brit. gall.; and 144 pots = 8 skieps = 1 barrel or toende = 3·83 Brit. bushels. Also 12 barrels = 1 last of corn = 5·739 Brit. quarters.

Egypt.—Of the weights, 144 dirhems = 12 oockeeyehs = 1 lb. or rutl = 15·75 oz. avoird.; and 400 dirhems = 1 oke or oockkah = 2·78 rutls = 2·75 lbs. avoird. Also 100 rutls = 1 cantar or ckuntar, from 98 to 99 lbs. avoird. The common cubit = 22·667 Brit. inches; the cubit used for Indian goods = 25 Brit. inches; the cubit of Constantinople used for European cloth = 26·5 Brit. inches. Of corn measure, 24 roobas = 6 weybehs = 1 ardeb = 4·847 Brit. bushels. But various other weights and measures are to be found in some parts of Egypt.

France.—The metrical system, whose multiples and subdivisions all proceed decimally, was instituted in 1795, and is founded upon the dimensions of the earth: the ten millionth part of the meridian arc between the pole and equator, being denominated a *mètre*, forms the unit of length. The other units, all derived from it, are, 1st, that of surface, the *are*; 2d, of solidity, the *stère*; 3d, of capacity, the *litre*; and, 4th, of weight, the *gramme*. The Latin derivatives *deci* to denote the tenth part, *centi* the hundredth, and *milli* the thousandth part, being prefixed to any of these units, serve to denominate its decimal subdivisions; while the sort of Greek derivatives *deca* to denote ten times, *hecto* an hundred, *kilo* a thousand, and *myria* ten thousand times, being prefixed, express its decimal multiples. Thus, a decimetre means the tenth of a metre, and a decametre is 10 metres. So far as it goes, a tolerably correct summary of this system is given in the preceding part of this article. But being exceedingly brief, and involving several terms very different from those actually used by the French, we have here endeavoured to state the matter so as to be more intelligible to the general reader.

The metre is then equal to 10 decimetres = 100 centimetres = 1000 millimetres = 1·093633 Brit. yard, or 39·37079 Brit. inches; and 32 metres = 35 Brit. yards nearly. Also 1000 metres = 100 decametres = 10 hectometres = 1 kilometre or metrical mile = 3280·899 Brit. feet = 1093·633 yards, or nearly 5 furlongs.

The are or metrical perch, consisting of 100 square metres, = 10 deciares = 100 centiares = 119·6033 Brit. sq. yards. Also 100 ares = 10 decares = 1 hectare = 2·471143 Brit. acres; and 17 hectares are nearly equal to 42 Brit. acres.

The stere or cubic metre = 10 decisteres = 1·308022 Brit. cubic yard; and 10 steres = 1 decastere ne litre or cubic decimetre = 10 decilitres = 100 centilitres = ·027052 Brit. cubic inches; and 50 litres are nearly 11 Brit. ga ns. Also 100 litres = 10 decalitres = 1 hectolitre = 2·751207 B . bushels; and 32 hectolitres are nearly equal to 11 Brit. qu ters, and 100 hectolitres = 10 kilolitres or cubic metres = 1 m alitre = 34·390086 Brit. quarters.

ne gramme is a weight equal that of 1 cubic centimetre of wa r at its maximum density. It contains 10 decigrammes = 100 ce grammes = 15·434 troy grains; and 1000 grammes = 100 de grammes = 10 hectogrammes = 1 kilogramme = 2·679514 lbs. tr = 2·204857 lbs. avoird. Also 100 kilogrammes = 10 myriagr mes = 1 metrical quintal = 220·486 lbs. avoird.; and 10 qu tals = weight of a cubic metre of water = 1 millier or marine to = 19 Brit. cwt. 2 qrs. 20 lbs. 13·75 oz.

ne *Système Usuel*, or Binary System, of the French, was introdu d in 1812, for the accommodation of retail trade, to make a so of compromise with the common people, who shewed an irreco ileable aversion to the innovations of the metrical or decimal sy em. It has the metrical standards for its basis; but their di sions, &c. instead of being decimal, are chiefly binary, that is, th proceed principally by continually halving or doubling some of ese standards, though partly according to other divisions of th old system; and instead of the metrical vocabulary, the names of ncient weights and measures are employed, annexing the term *u l* to each. Thus, the toise usuelle = 2 metres = 78·74158 B . inches. The pied usuel is one sixth of the toise, and is subdi ded into twelfths or inches, &c. The aune usuelle = 12 decim res = 1·2 metre = 47·2449 Brit. inches. The litron usuel = l re = 1·7608 Brit. pint. The Boisseau usuel is one eighth of tl hectolitre, and = 2·7512 Brit. gallons. The livre usuelle is h the kilogramme, and = 1·10243 lb. avoird. The halves, quart , eighths, &c. of the most of the above are also in use. A su mary of the ancient French system will be found in the prec ng part of this article.

rankfort on the Maine.—Of the weights, 128 drachmes = 32 l s = 2 marks = 1 heavy lb. = 1·1143 lb. avoird. The light lb. is milarly divided, but only = 1·0318 lb. avoird., so that 108 of t light lbs. make only 100 of the heavy or centner weight. The C ogne mark, here reckoned = 3611 grains troy, is used for gold a silver. The Frankfort foot contains 11·42 Brit. inches, and t ell 21·54. The Brabant ell is generally used for Dutch goods, a the Paris aune for French. Eighty old or 90 new mass (each o schoppen) are equal to 20 viertels = 1 ohm = 31·57 Brit. gall.; a 16 sechters = 8 metzen = 4 simmers = 1 malter or achtel = 3 Brit. bushels.

enoa.—There are two sorts of pounds, the peso sottile lb., and t peso grosso lb. The latter is a tenth part heavier than the forr r, so that the cantaro of 100 lbs. peso sottile = 69·89 lbs. avoird., a the cantaro of 100 lbs. peso grosso = 76·88. The latter is u d for bulky commodities, and the former for gold, silver, and a articles of small bulk. The palmo = 9·725 Brit. inches, and 2 33 palmi = 1 braccio. The canna is of three sorts: the canna p cola used by tradesmen = 9 palmi, the canna grossa of the merc nts = 12 palmi, and the custom-house canna = 10 palmi. Of c n measure, 96 gombette = 8 quarti = 1 mina = 3·31 Brit. bushe Also 100 pints = 2 barili = 1 mezzarola of wine = 32·67 t. gall.; and 64 quateroni = 4 quarti = 1 oil barile = 14·23 t. gall.

ermany.—Considerable diversity of weights and measures is be found in the various states into which this extensive coun is divided, and the most important of them will be found iced separately. But not a few of their standards, though difing in amount, are similar in their multiples and subdivisions. the weights, 1024 hellers = 312 pfennings = 128 quentins = loths = 16 ounces = 2 marks = 1 commercial lb.; and 5760 ins = 288 scruples = 96 drams = 12 oz. = 1 apothecaries' lb.; 4352 eschen = 512 hellers = 256 pfennings = 64 quentins = loths = 8 oz. = 1 Cologne mark = 3608 grains troy. By this d and silver are weighed; and the fineness of gold is expressed 24th parts or carats as in Britain, but the fineness of silver by th parts. For jewellery there is a carat of 3·171 grs. troy. Of measures, 144 inches = 12 feet = 6 ells = 2 clafters = 4 ruthe. e Rhinland foot used by surveyors = 12·36 Brit. inches; the g mile = 10,126 Brit. yds., the short mile = 6859, and the graphical mile = 8101 Brit. yds. The Rhinland morgen of d = 10,185 Brit. sq. yds.

Gibraltar.—Besides the British standards, the following Spanish also used: The arroba = 26 lbs. avoird.; the quintal = 100 = 101·75 lbs. avoird.; the corn fanega = 1·55 Brit. bushel; pipe of 117 gallons = 105 Brit. gall.; the liquid arroba = 7 Brit. gall.; and the wine gallon = 1·094 Brit. gall.

Goa.—The same as in Portugal, except that the candy of 20 unds = 495 lbs. avoird. This, in the measurement of grain, is ckoned to be nearly 14 Winchester bushels.

Greece.—The same as in France.

Guiana (British).—In general the same as in Britain; but the following, originally introduced by the Dutch, are also used: the lb. = 1·09 lbs. avoird.; and the ell of 26 inches = 27 British inches.

Guiana (Dutch).—In general the same as in Holland, but chiefly upon the old system.

Hamburg.—Of the weights, 128 drachmes = 32 loths = 16 oz. = 2 marks = 1 lb. = 1·0682 lb. avoird.; 112 lbs. = 8 lisponds = 1 centner = 119·64 lbs. avoird.; and 5 centners = 2 shipfunds. Ten lbs. = 1 stone of wool or feathers = half a stone of flax. Of butter, 280 lbs. form the great, and 224 the small tonne. A pipe of oil is reckoned at 820 lbs. Gold and silver are weighed by the Cologne mark, and their fineness valued as explained under the head Germany. Of measures, 6 palms = 2 feet = 1 ell = 22·578 Brit. inches. The Rhinland foot of engineers and surveyors = 12·36 Brit. inches. The Brabant ell, commonly used for piece goods, = 27·585 Brit. inches. Also 160 quarters = 40 stubgens = 20 viertels = 5 eimers = 4 ankers = 1 ahm = 31·87 Brit. gall.; and 24 ankers or 6 ahms = 1 fuder. Of wine, 6 tierces = 4 oxhofts or hogsheads = 1 faas; but these are of various sizes. Of corn, 160 spints = 40 himtens = 20 faas = 10 scheffels = 1 wisp or wispel = 29 Brit. bushels; two wisps = 1 last of barley or oats = 7·25 Brit. quarters; and 3 wisps = 1 last of wheat or rye = 1 stock of barley or oats = 10·87 Brit. quarters.

Hanover.—The lb. = 1·073 lb. avoird.; 112 lbs. = 1 centner; and 20 lbs. = 1 stone of flax or 2 stones of wool. Also 600 lbs. = 51 stubgens = 2 tonnes of honey; and 3360 lbs. = 240 lisponds = 12 shipfunds = 1 last. The Cologne mark is used for gold, silver, and silk. Two feet = 1 ell = 22·91 Brit. inches; the mile = 6·5676 Brit. miles. The morgen land measure = 2·5625 Brit. roods. Also 80 kannen = 40 stubgens = 4 ankers = 2·5 eimers = 1 ahm = 34·24 Brit. gallons; and 6 ahms = 4 oxhofts = 1 fuder of wine. Of corn, 96 himtens = 16 malters = 2 wisps or wispels = 1 last = 82 Brit. bushels.

Hayti.—*Port-au-Prince.*—Principally the old system of France, together with the old English wine gallon.

Hesse-Cassel.—The lb. = 17·08 oz. avoird. The ell = 22·59 Brit. inches; the acre = ·5894 Brit. acre; the liquid ohm = 34·94 Brit. gall.; and 16 corn metzen = 4 himtens = 1 viertel = 4·42 Brit. bushels.

Hesse-Darmstadt.—Two lbs. = 1 French kilogramme = 2·20486 lbs. avoird. Ten feet = 1 klafter = 2·5 metres = 8·2023 Brit. feet; five ells = 3 metres = 3·2809 Brit. yds.; four morgens = 1 hectare = 2·47114 Brit. acres. The liquid ohm = 160 litres = 35·22 Brit. gallons; the corn malter = 1·28 hectolitre = 3·522 Brit. bushels.

Holland.—In 1820, the decimal system of France was introduced, but with the old Dutch nomenclature, as explained under the head Belgium. Of the old weights still used in many places, 10,240 aas = 320 engels = 16 oz. = 2 marks = 1 Dutch lb. troy = 1·0851 lb. avoird. There are also 16 oz. in the commercial lb. = 1·0893 lb. avoird., and 100 commercial lbs. = 1 centner. The old Amsterdam foot = 11·15, and the ell = 27·08 Brit. inches; the Rhinland foot = 12·36, and the Flemish or Brabant ell = 27·58 Brit. inches. Nineteen Dutch leagues make one degree of the meridian.

Japan.—The weights are almost the same as in China. The inc = 6·25 Brit. feet; but the measures of capacity have not been compared.

Java.—In this and the other Dutch colonies in India, the weights of China are ordinarily employed; but the pecul, instead of being exactly 133·33 lbs. avoird. is = 135·625 lbs. Of rice, the coyang = 3581 lbs. avoird. and the timbang = 10 sacks = 5 peculs = 678·125 lbs. The Dutch troy mark of 9 reals, = 3798 Brit. troy grains, is used for gold and silver. The foot = 12·36, and the ell = 27·75 Brit. inches. The kanne, liquid measure, = ·3282 Brit. gall., and 396 rands = 1 leaguer of arrack = 133·33 Brit. gall.; but 360 rands = 1 leaguer of wine.

India.—Grain is generally sold by weight, as also liquids, except wines and spirits, which at all the three presidencies are sold by British measures. Of the Bengal weights, 940 chittacks = 40 seers = 1 factory maund = 74·67 lbs. avoird. or two thirds of a British cwt. The bazaar maund is one tenth greater than the factory, and similarly divided. Gold and silver are weighed by the new tola or sicca of 180 grains troy. Two cubits = 1 guz = 1 Brit. yd. The coss or mile of Bengal = 2000 yards, and 1600 sq. yds. = 20 cottahs = 1 biggah. At Bombay 40 seers = 1 maund = one quarter of a British cwt., and 20 maunds = 1 candy = 5 cwts., which in corn is counted at 24·5 Brit. bushels. At Madras, 320 pollams = 8 vis = 1 maund = 25 lbs. avoird., and 20 maunds = 1 candy. The covid = 18·6 inches, but the British yard is used for cloth; and in land measure, 24 maunies = 1 cawney = 6400 Brit. sq. yds. Also 320 measures = 400 marcals = 80 parahs = 1 garse or gursay. The marcal = 750 Brit. cubic inches. When grain is sold by weight, 9256·5 lbs. avoird. are reckoned to the garse.

Commercial Weights, &c. of India, and of several adjacent States, with their equivalents in British, Bengal Factory, Madras, and Bombay Weights.

Commercial Weights, &c.	Avoirdupois.			Bengal Factory.			Madras.			Bombay.

Ionian Isles.—The present British system was introduced in 1828, when the libbra sottile was made equal to 1 lb. troy, the libbra grossa to 1 lb. avoird., the talanto to 100 lbs. avoird., the stadio of 40 carnaco to 1 Brit. furlong, the barrel to 16 Brit. gallons, and the kilo of corn to 1 Brit. bushel. Of the old weights, 44 okes = 1 quintal = 123·15 lbs. avoird., or 40 okes = 1 cwt. nearly. Of the old measures, the Zante braccio for cloth = 27·18 Brit. inches, the silk braccio = 25·37 Brit. inches; the Zante barile = 14·68, and the Corfu barile = 15 Brit. gallons. Also 8 misure = 1 corn moggio of Zante = 4·63 Brit. bushels. In land measure, 24 zappade = 8 misure = 1 moggio = 2·4 Brit. acres.

Lubeck.—The Cologne mark of 3608 troy grains is used for gold and silver, and 112 lbs. = 8 lisponds = 119·67 lbs. avoird. Two feet = 1 ell = 22·7 Brit. inches; and 80 kannes = 40 stubgen = 20 viertels = 1 ahm = 31·87 Brit. gall. Also 96 scheffels = 24 barrels = 8 dromts = 1 last of wheat or rye = 11·04 Brit. quarters. The last of oats = 12·95 quarters, and is similarly subdivided.

Lucca.—The common lb. = 0·7448 lb. avoird., but the lb. peso grosso = 8·234 lbs. avoird. or 11 Leghorn lbs. The braccio for woollens = 23·8 Brit. inches, but that for silk is an inch less. There are 4 braccio in the canna. The coppo for oil = 21·97 Brit. gall. Wine is sold by the Leghorn barile of 20 fiasci, and corn by the staja = two thirds of a Brit. bushel.

Madeira.—In general the same as in Portugal; but in corn measure 23 alquieres are = 24 of Lisbon, and in wine measure 12 almudos are = 13 of Lisbon.

Majorca.—One hundred rottolos or lbs. = 1 cantaro Berberesco = 88·2 lbs. avoird.; 104 rottolos = 4 arrobas = 1 quintal = 91·73 lbs. avoird.; and 312 rottolos = 3 quintals = 1 carga. Also 108 rottolos = 12 quartins or cortans = 1 odor of oil. The canna = 67·5 Brit. inches. Of wine, 6·5 corters = 1 quartin = 5·97 Brit. gall.; and 6 barcellas of corn = 1 quartera = 1·94 Brit. bushel.

Malacca.—One hundred catties = 1 pecul = 135 lbs. avoird.; 3 peculs make 1 bahar; and 500 gantons = 50 measures = 1 last = 29 Brit. cwts. nearly. Also 40 peculs = 1 coyau of salt or rice. A kip of tin = 41 lbs. avoird. The buncal, = 832 grains troy, is used for gold and silver. The covid = 18·125 Brit. inches.

Malta.—One hundred rottoli or lbs. = 1 cantar = 174·5 lbs. avoird. Gold and silver are weighed by the lb. of 12 oz. = 4886 grains troy. Eight palmi = 1 canna = 82 Brit. inches; and 16 square tumoli = 1 salma land measure = 4·44 Brit. acres. The wine barile contains 9·17, and the oil caffiso 4·375 Brit. gall. Two caffisos make a barile. The salma corn measure = 7·875 Brit. bushels.

Marocco.—The rottolo or commercial lb. = 1·19 lb. avoird., and 100 such lbs = 1 quintal. The market lb. is one half heavier, or = 1·785 lb. avoird. By it iron, bees' wax, and provisions are sold. The canna for cloth = 21 Brit. inches, but the measures of capacity are very variable.

Mauritius.—In government affairs the British system is used, but in ordinary business something near the old system of France, reckoning the quintal of 100 lbs. poids de marc = 108 lbs. avoird.; 20 quintals = 1 French ton; 100 lbs. French to the bag of coffee, 150 to the bag of rice, and 250 to the bale of cotton. Also 15 French feet are reckoned = 16 Brit. feet, 7 aunes = 9 Brit. yds., 1 arpent = 1·04375 acre, one velt = 2 old English wine gallons, and 30 velts = 1 cask.

Mecklenburg.—The weights are chiefly those of Lubeck and Hamburg, but 100 Rostock lbs. = 1 Brit. cwt. There are 2 feet in the Rostock ell = 22·67 Brit. inches, and 1 scheffel of corn = 1·07 Brit. bushel. The liquid measures are those of Lubeck.

Mexico.—In general the same as in Spain; but the British yd. and French aune are also in use for European goods.

Minorca.—The weights and dry measures are the same as in Majorca; and, except the gerra or jar of two quarters, = 2·65 Brit. gall., the other measures are the same as in Spain.

Mocha.—Of the weights, 150 maunds = 15 frazils = 1 bahar = 450 lbs. avoird.; 48 carats = 3 coffola = 2 miscals = 146·74 grains troy; 10 coffolas = 1 vakia, and 87 vakias = the weight of 100 Spanish dollars. The covid = 19, the guz = 25 Brit. inches; 8 noosfias = 1 gudda = 1·8 Brit. gallon; and 40 kellas dry measure = 1 tomand, which, of rice, is reckoned to weigh 168 lbs. avoird.

Modena.—The Modena libbra or lb. = 0·7045 lb.; the Reggio lb. = 0·7274 lb. avoird., and 100 lbs. = 1 quintal. The Modena braccio = 24·31; and the braccio of Reggio = 20·85 Brit. inches. In land measure, 72 tavole = 1 biolca = 2·8036 Brit. roods. Corn is sold by the stajo, = 1·94 Brit. bushel.

Moldavia.—In general the same as in Turkey; but in common trade 25 okes of Galatz are reckoned = 2 Russian-poods; 2400 okes = 7 centners = 700 lbs. of Vienna.

Montevideo.—Same as in Spain.

Mozambique.—One frazil = 12 lbs. avoird., and 20 frazils = 1 bahar.

Muscat.—Twenty-four cuchas = 1 maund = $8\frac{3}{4}$ lbs. avoird.

Naples.—One hundred rottoli or lbs. = 1 cantaro grosso = 196 45 lbs. avoird.; 1800 oz. = 150 lbs. = 1 cantaro piccola = 106·07 lbs. avoird.; and 7200 acini = 360 trapesi = 12 oz. = the lb. of 4950 grains troy, by which gold and silver are weighed. Of the measures, 96 inches = 8 palmi = 1 canna or ell = 83·05 Brit. inches; 15 palmi make 2 passi, and 7000 palmi = 1 mile = 2018 Brit. yds. There are 900 sq. passi in the moggia of land = ·8315 Brit. acre. Sixty caraffi = 1 baril of wine or brandy = 9·6 imp. gall.; 24 barili = 2 botte = 1 carro; 14 barili = 1 pipe; and 256 quarti = 16 staja = 1 salma of oil = 34·91 Brit. gall., and is reckoned to weigh 324 lbs. avoird. Four quarti of corn = 2 mezzetti = 1 tomolo = 1·519 Brit. bushels. At Gallipoli, 320 pignatti = 10 staja = 1 salma of oil = 34·11 Brit. gall. The salma at Bari = 36·42 such gallons.

Nassau.—The standards are founded on the metrical system of France. Ten inches = 1 foot = half a metre = 19·685 Brit. inches; 10 feet = 1 perch, and 100 square perches = 1 morgen = 25 ares = ·6178 Brit. acre.

New Brunswick.—Same as in Britain.

Newfoundland.—Same as in Britain.

New Granada.—Same as in Spain.

Norway.—The same as in Denmark.

Nova Scotia.—The same as in Britain.

Oldenburg.—The weights are those of Hamburg. Twelve inches = 1 foot = 11·65 Brit. inches; and the ell contains 22·76 of same inches. Also 104 kannes = 4 ankers = 1 ohm; 3 ohms = 2 oxhofts; and 144 scheffels = 18 tonnes = 12 malters = 1 last = 80·69 Brit. bushels.

Parma.—Of the weights, 300 ounces = 25 lbs. = 1 rubbio = 18·08 lbs. avoird. The braccio for measuring cloth = 25·35 Brit. inches, which exceeds that used for silk by 1·95 inch. There are 12 inches in the braccio di ligno used by surveyors, = 21·34 Brit. inches; and 6 bracci = 1 perch. Also 288 sq. perches = 72 tavole = 6 tari = 1 biolca = nearly ·75 Brit. acre; and 16 quarterole = 1 stajo of corn = 1·413 Brit. bushel.

Persia.—The weight chiefly used in commerce is the batman, which not only is of different amount in different districts, but depends also on the kind of article to be weighed. At Tabriz, 600 miscals = 300 derhams = 6 rattles = 1 batman = 6·34 lbs. avoird., which is only half the batman of Cherray. There is a derham of nearly 150 grains troy, by which gold and silver are weighed, and wh exceeds the derham of Bushire by nearly 7 grains. Pearls are eighed by the abas of 2·25 troy grs. The measures are not les variable than the weights. The guz or common cubit = 25 Br inches, and the royal guz is one half longer. The archin of Ta iz = 44 Brit. inches. There are 20 leagues or parasangs in a d ree of the equator; but it is by the fursoch or augage, that is, e space of about four or five Brit. miles walked over by a hor in an hour, that moderate distances are usually reckoned. Gr ter distances are estimated by the day's march of a caravan, wh may be about 30 miles. In corn measure, 200 sextarios = chenicas = 25 capichas = 1 artaba = 1·939 Brit. bushels.

ru.—The same as in Spain.

ilippine Isles.—The same as in Spain, except that the Chinese pe is sometimes used.

land.—Of the weights, 128 drachms = 32 loths = 16 oz. = 1 lb. = 0·89414 lb. avoird.; 32 lbs. of Poland = 1 stone, and 160 suc lbs. = 1 centner. The Cologne mark is used for coined gold an ilver, but the Warsaw mark = 3113 grains troy for the uncoi d. Two feet = 1 ell or lokci = 22·68 Brit. inches. The mi is the twentieth part of a degree of the meridian. There are 30 perches in the acre or morgen, = 1·384 Brit. acre: and 30 mo ens make 1 wloka. Also 16 liquid kwaterkas = 4 kwartas = 1 ga ec = 4 French litres = 0·88039 Brit. gall.; and 25 garniecs = ecsksa. Of corn, 128 kwartas = 32 garniecs = 4 cwiercs = 1 ko c = 3·5214 Brit. bushels.

pedom or Papal States.—Of the commercial weights, 6912 gra = 288 denari = 12 once = 1 Roman lb. = ·7477 lb. avoird. Th same lb. is also used by apothecaries and for gold and silver; an 00 such lbs. = 10 decine = 1 quintal. The foot = 11·72 Brit. inc s; 8 palmi = 1 mercantile canna = 6·52917 Brit. feet. The R an mile = 1628 Brit. yds. Also 128 fogliette = 32 boccali = barile of wine = 12·84 Brit. gall.; 80 boccali = 1 soma of oil 36·14 Brit. gall; and 88 quartucci = 22 scorzi = 4 quarte = 1 c n rubbio = 8·1 Brit. bushel. In Ancona, 100 lbs. = 73·75 lbs. av d.; the braccio = 25·33 Brit. inches; and 24 boccali = 2 ba = 1 wine soma = 18·9 Brit. gall. Also 8 coppe = 1 corn ru o = 7·87 Brit. bushels. In Bologna, the lb. = ·798 lb. avoird., an he foot = 15 Brit. inches.

rtugal.—Of the commercial weights, 32 marks = 16 oz. = 1 ar el or lb. = 1·0119 lb. avoird.; and 32 arratels = 1 arroba. Th e are 4 arrobas in the quintal, and 54 in the tonelada. The ap ecaries' lb. is only three fourths of the commercial. There ar 8 inches in the palmo craveiro, = 8·622 Brit. inches; the pe or ot = 1·5 palmo; 5 palmos = 1 varo; and though three palmos ar usually said to form the varo, it is more nearly 26·67 Brit. in s. Ten palmos = 1 braço; the mile = 2253 Brit. yds.; and 3 es = 1 league. Of land, 4840 square varos = 1 geira; and 7 ge s make nearly 10 Brit. acres. Of liquids, 48 quartilhos = 12 ca las = 2 pots = 1 almude of Lisbon = 3·64 Brit. gall.; there ar 8 almudes in the baril, 26 in the pipe, and 52 in the tonelada. In ry measure, 240 quartos = 60 alquieres of Lisbon = 15 fanega = 1 moyo = 22·39 Brit. bushels. The almude of Oporto = 5 Brit. gall., and the alquiere of Oporto = ·465 Brit. bushel.

ussia.—Of the commercial weights, 128 quintins = 32 loths = Cologne marks = 1 lb. = 1·0311 lb. avoird.; and 110 lbs. = 1 ce ner or quintal = 113·42 lbs. avoird. There are 4000 lbs. in th hip last; and the apothecaries' lb. is only two thirds of the co mercial. The Cologne mark is used for gold and silver. The R land foot = 12·356 Brit. inches; the ell = 26·26 of such in es; and 2000 perches = 1 mile = 8237 Brit. yds. There are 1 sq. perches in the morgen or acre, = 3054 Brit. sq. yds.; and 30 orgen = 1 hufe. Also 120 quarts = 4 ankers = 2 eimers = 1 li d ohm = 30·23 Brit. gall.; 3 eimers = 1 oxhoft; 100 quarts = tun of beer; and 48 quarts = 16 metzen = 1 corn scheffel = 512 Brit. bushel. Various old measures are still partially in e.

usso-German commercial league or Zoll-Verein is composed of nhalt Bernbourg, Anhalt Cothen, Anhalt Dessau, Baden, Bava , Birkenfeld (part of Oldenburg), Frankfort, Hesse Cassel, H se Darmstadt, Hesse Homburg, Hohenzollern Hichengen, H enzollern Sigmaringen, Nassau, Prussia, principalities of R ss, Saxony, Saxe-Altenburg, Saxe-Coburg Gotha, Saxe-M ningen, Saxe-Weimar, Schwarzburg Rudolstadt, Schwarzb Sondershausen, Waldeck (exclusive of Pyrmont), Würte erg. The basis of their tariff is the centner of Baden = 50 rench kilogrammes, and divided into 100 pounds or livres u lles of France. Hence the zoll centner of 100 lbs. = 1 2429 lbs. avoird. The following relative values are given in th tariff:—

935·422 zoll lbs. = 1000 Prussian lbs.
1120· ... ... = 1000 Bavarian lbs.
2000· ... ... = 1000 kilogrammes.
935·456 ... ... = 1000 Würtemberg lbs.
933·673 ... ... = 1000 Saxon (Dresden) lbs.

Or 14 zoll lbs. = 15 Prussian lbs. nearly.
28 ... ... = 25 Bavarian lbs.
2 ... ... = 1 kilogramme.
14 ... ... = 15 Würtemberg nearly.
14 ... ... = 15 Saxon (Dresden) lbs. nearly.

Russia.—Of the weights, 96 zolotnicks = 32 loths = 1 lb = ·90264 lb. avoird. With this lb., which is used for most purposes, gold and silver are also weighed, it being divided into 6528 grains. The Nuremberg lb. of 5527 grains troy is used by the apothecaries. The British and Dutch feet and inches are employed. The Russian foot = 13·75 Brit. inches; 16 verchoks = 1 archine for cloth = 28 Brit. inches; and 1500 archines = 500 sagenes = 1 verste or mile = 1167 Brit. yds. Also 2400 sq. sagenes = 1 deciatine = 2·7 Brit. acres; and 100 tcharkeys = 2·705 Brit. gall. Of corn, 64 garnietz = 32 tchetverkas = 8 tchetveriks = 4 payaks = 2 osmines = 1 chetwerk = 5·77 Brit. bushels. Various old standards are partially in use in different parts of the empire.

Sardinia.—In Turin, 12 oz. = 1·5 mark = 1 lb. = ·8133 lb. avoird.; 25 lbs. = 1 rubbio; and the mark of 3795 grs. troy is used for gold and silver. The raso or ell = 23·6 Brit. inches; the mile = 2697 Brit. yds.; the giornate = ·938 Brit. acre; the wine rubbio = 2·07 Brit. gall.; and the corn sacco = 3·17 Brit. bushels. In Nice, 150 lbs. = 1 quintal = 103·14 lbs. avoird.; the ell = 3·8975 Brit. feet; 12 rubbi = 1 charge = 20·75 Brit. gall.; but the charge of corn = 4·4 Brit. bush. In Cagliari, 12 oz. = 1 lb. = ·875 lb. avoird.; the raso = 21·63 Brit. inches, and the restiere = 4·04 Brit. bushels.

Saxony.—In Dresden, the lb. = 1·0293 lb. avoird.; 110 lbs. = 1 centner; the mark = 3602 grs. troy; two feet = 1 ell = 22·3 Brit. inches; 3200 feet = 1 mile = 9914 Brit. yds.; the morgen or acre = 1·261 Brit. acre; the liquid eimer = 14·84 Brit. gall.; the scheffel = 2·859 Brit. bushels. In Leipzig, 32 loths = 1 lb. = 1·0301 lb. avoird.; the centner = 110 lbs. = 113·32 lbs. avoird. Two feet = 1 ell = 22·24 Brit. inches; 60 ells = 1 schock; the liquid eimer = 16·69 Brit. gall.; the old scheffel for corn = 3·812 Brit. bushels. The Dresden scheffel, which is one third greater, is now the general standard.

Siam.—The common weight is the catty = 2·67 lbs. avoird., which is double the Chinese catty; but the pecul, containing only 50 catties, is just equal the Chinese pecul. Also 8 spans = 4 cubits = 1 fathom = 6·5 Brit. feet; 20 fathoms = 1 sen; but a square area of 20 fathoms to the side is likewise named a sen.

Sicily.—The cantarro grosso = 192·53 lbs. avoird.; the cantarro sottile = 175·03 lbs. avoird. The lb. = ·7014 lb. avoird. Gold and silver are weighed and valued as at Naples; 94 cubic French feet of the old standard = 5 salmes = 1 ship ton. Oil is sold in Messina by the caffiso, = 2·58 Brit. gall. The canna = 81·35 Brit. inches; the wine tonna = 31·24 Brit. gall.; the corn salma = 7·61 Brit. bush., and the salma grossa of Leghorn = 9·47 Brit. bushels.

Sincapore.—The Chinese pecul of 133·33 lbs. avoird. is the usual weight. The covid for cloth = 18 Brit. inches; the gantang, by which corn, fruit, and liquids are occasionally sold, = 1·04 Brit. gall. European commodities are often sold by British weights and measures.

Spain.—Two marks = 1 lb. = 1·01443 lb. avoird.; the arroba consists of 25, and the quintal of 4 lbs. The mark used for gold and silver is = 3550 grains troy. Twelve pulgados = 1 Burgos foot = 11·128 Brit. inches; 4 palmos = 1 vara or ell = 33·38 Brit. inches. The estadale = 12 feet; 8000 varas = 1 league = 7418 Brit. yds. A degree is divided into twenty marine leagues; 5378 sq. varas = 1 aracada of vine land; and 6000 sq. varas = 1 fanegada of corn land. The greater or wine arroba = 3·54 Brit. gall., the less or oil arroba = 2·77; the pipe = 27 of the greater arrobas, or 34·5 of the less: the corn fanega = 1·55 Brit. bushels; and 12 fanegas = 1 cahiz. But a variety of local standards is also in use.

Sweden.—The lb., victual weight, = 6563 grains troy; the lispund contains 20, the sten 32, the centner 120, the waag 165, and the skeppund 400 such lbs. Two feet = 1 ell = 23·38 Brit. inches; 8 ells = 1 ruthe; 2250 ruthes = 1 mile = 11,689 Brit. yds.; the tunnaland = 1·22 Brit. acre. The liquid kann = ·5756 Brit. gall.; the fuder contains 300, the pipe 180, the oxhufvud 90, and the ahm 60 kanns. The corn tunna = 4·029 Brit. bushels. But various other measures and local standards are in use.

Switzerland.—In 1837 the 12 cantons, Berne, Zürich, Lucerne, Friburg, Zug, Soleure, Basel, Aargau, Thurgau, Schaffhausen, Glarus, and St Galen, adopted the following standards, founded on the decimal system of France: 32 loths = 1 lb. = half a kilogramme = 1·1024 lb. avoird.; 2 feet = 1 ell = 6 decimetres; and 1 stund = 4800 metres = 5249 Brit. yds. The liquid mass = 1·5 litre = 2·64 Brit. pints; ten mass of corn = 1 viertel = 15 litres = 1·65 Brit. peck. In Geneva, besides the French system, 100 lbs gros poids = 121·43 lbs. avoird.; 100 lbs. petit poids = 101·19 lbs.

Weimar. avoird. The winechar = 120·71 Brit. gall.; the coup of corn = 2·13 Brit. bushels.

Tripoli.—One hundred rottoli = 1 cantar = 109·71 lbs. avoird.; the caraffa of oil weighs 3·125 rottoli. The great pik = 26·42, and the small = 19·03 Brit. inches; the wine barile = 14·25 Brit. gall.; and 4 temen = 1 corn hueba = 2·95 Brit. bushels.

Tunis.—One hundred rottoli = 1 cantaro = 111·75 lbs. avoird.; for cotton the pik or ell = 19·23, for silk and linen = 25, and for woollen = 26·5 Brit. inches. The wine millerole = 14·15, and the oil mettar = 4·27 Brit. gall. The corn caffiz = 1·918 Brit. quarter.

Turkey.—The oke = 2·8286 lbs. avoird.; 1 oil almude should weigh 8 okes; 100 rottoli = 44 okes = 1 quintal = 124·46 lbs. avoird. The great pik = 27·9, the small = 27·06 Brit. inches; the berri or mile = 1826 Brit. yds.; the liquid almude = 1·143 Brit. gall.; the corn fortin = 3·84 Brit. bushels.

Tuscany.—The quintal or cantaro = 100 lbs. = 74·86 lbs. avoird.; 20 soldi = 1 braccio = 22·979 Brit. inches; the mile = 1808 Brit. yds.; the sacato of land = 5928 Brit. sq. yds.; the baril for wine = 10·03, and for oil = 7·36 Brit. gall. The corn stajo = 2·676 Brit. pecks; and 24 staja = 1 moggio.

United States of America.—Chiefly the same as in England prior to the imperial system. But instead of the cwt. they generally use simply 100 lbs. which are sometimes called a quintal. The barrel of flour weighs 196 lbs.; the hhd. of Indian meal 800 lbs.; and the barrel of salt meat 200 lbs.

Wallachia—The weights are those of Moldavia. The killow of Brailow, of about 400 ocche = 1·5 killow of Galatz = 18 killows of Constantinople = 9 sacchi of Leghorn. In other respects the same as in Turkey.

West Indies (British).—In general the same as in Britain; but Spanish measures are partly used in Trinidad, and the old system of France in St Lucia.

West Indies (French).—Same as in France.

West Indies (Dutch).—Chiefly the old system of Amsterdam. In Curaçoa the Spanish varo is also employed.

West Indies (Danish).—Same as in Denmark. The British yard and French aune are sometimes employed.

West Indies (Swedish).—Chiefly the same as in Sweden.

Würtemberg.—The lb. = 1·0314 lb. avoird.; the foot = 11·25 Brit. inches. The toise = 6 feet; the ell = 24·18 Brit. inches. The mile is the fifteenth of a degree. The morgen or acre = 31·518 French ares; and 1·5 morgen = 1 juchart. The fuder of wine = 388·16 Brit. gall. The scheffel of corn = 4·88 Brit. bushels.

For further particulars, we beg to refer to Kelly's Metrology, and his Universal Cambist; the Parliamentary Reports, particularly those relating to the Board of Trade; Buchanan on Weights and Measures; M'Culloch's Commercial Dictionary; and Waterston's Manual of Commerce, which contains much valuable matter within a very small compass. (E. E. E.)

WEIMAR, a city, the capital of the grand duchy of that name, in Germany. It stands on the river Ilm, and is surrounded with hills, some of which are covered with woods. The buildings are not remarkable, but are on the whole in a better style and condition than is to be seen in most of the towns in Germany of the same extent. The grand duke has a palace in an unfinished state, but with a valuable library, open to all the inhabitants; and some of the state-apartments are elegantly furnished. The liberal feelings of the reigning family have, by their patronage of the most accomplished men of Germany, given a celebrity to their capital to which it could not have attained on any other account. They brought there men like Schiller, Wieland, Herder, Goethe, and several others, who formed points of attraction, which drew towards them the minds of all literary Germans, and thus diffused a spirit and tone of the most elevating nature. The chief trade is that of composing and printing useful works, in a large establishment, in which are employed several hundred workmen, as authors, engravers, letter-founders, lithographers, and printers. The maps issued from it are generally very correct, and sold at low prices, to suit the finances of the great class of the people. The periodical works on surgery and medicine, and the geographical Ephemeriden, are of high reputation, and issued at similar low rates. One of the most attractive objects is the theatre. Here the plays of Schiller and of Goethe were first performed; and this theatre was during many years under the direction of the latter. Though but a small house, nothing can be more appropriate than the building, the decorations, and the stage accuracy in the common representations.

Weimar contains two Lutheran churches, a chapel for the Catholics, and for the Greeks, with a Jews' synagogue. It is well furnished with schools for the several degrees of instruction, and prepares the pupils for the university of Jena, within the dominions of the same prince. There are many charitable institutions, such as an orphan-house, and several hospitals and poor-houses. At Belvedere, the prince has some very fine gardens, with green and hot-houses, and a fine collection of exotic plants. This forms one of the pleasant promenades by which the inhabitants of Weimar are gratified. The city being on the high road from Frankfort to Leipzig, is a great thoroughfare, and furnishes good accommodation for strangers at the hotels. In 1838 the inhabitants amounted to about 12,000. Long. 12. 45. 5. E. Lat. 50. 59. 12. N.

WEISK, a circle of the province of Wologda, in Russia, is bounded on the north-east by Archangel, on the east by Ustjug and Totma, on the south by Kadnikow, on the west by Novogorod, and on the north-west by Olonetz. It extends over 11,060 square miles, comprehends one city, two market-towns, 390 villages, and 68,750 inhabitants. The soil is generally poor, but near the rivers there is some good pasture-land. There are in it some manufactures of hardware. The capital is the small city of the same name on the river Waga. It scarcely contains more than 1200 inhabitants. It is 956 miles from St Petersburg. Long. 41. 45. E. Lat. 60. 40. N.

WEISSENSTEIN, a circle in the Russian province of Esthonia, formerly called Jerwin. It extends in north latitude from 58° 35′ to 59° 12′, and in east longitude from 25° 4′ to 26° 22′, and comprehends 924 square miles, having one town, eight villages, and ninety-one hamlets, with 27,240 inhabitants. The soil is good, and especially near the rivers, where there is excellent pasture for horned cattle. The capital is the town of the same name on the river Weissenstein. Long. 25. 27. E. Lat. 58. 51. 30. N.

WELDON, a market-town of the county of Northampton, in the hundred of Corby, seventy-three miles from London. It consists of two portions, distinguished as Great and Little Weldon, but the latter is the more populous. The river Nen has its source near the town. It contains a good market-house, occupied on Wednesday. The inhabitants amounted in 1821 to 819, and in 1831 to 778.

WELIKIJO-LUKI, a circle of the Russian government of Pfkow, extending in north latitude from 55° 54′ to 56° 50′, and in east longitude from 29° 23′ to 30° 45′. It is watered by the river Lowat, and many of its tributary streams; is generally level, in part undulating, and abounding in woods and morasses. The capital is the city of the same name, on the river Lowat, at the point where the Kolomenka falls into that stream. It has four stone and three wooden churches, 400 houses, and 3860 inhabitants, who are employed in tanning the peculiar leather of Russia, and trade in flax and hemp extensively. It is 308 miles from St Petersburg. Long. 30. 20. E. Lat. 56. 22. N.

WELISH, a circle of the Russian government of Witebsk. It extends in north latitude from 55° 25′ to 56° 2′, and in east longitude from 30° 13′ to 31° 6′. It contains one city and 1013 villages, with 56,400 inhabitants. The principal river is the Duna, which receives the waters of the Mescha and the Welish, as well as the overflowing of the lakes Us-ma and Tschiplia. The capital is a city of the same name on he Duna, at the spot where the Welishka falls into that str m. It is an ancient and ill-built town, with a Greek an Catholic church, and a synagogue. It contains 4800 in bitants, a fourth part of whom are Jews. It is 430 miles fro St Petersburg. Long. 31. 48. E. Lat. 55. 36. N.

ELL, a hole under ground, usually of a cylindrical figu and walled with stone and mortar. Its use is to collec he water of the strata around it.

ELL, an apartment formed in the middle of a ship's hol to enclose the pumps, from the bottom to the lower de s. It is used as a barrier to preserve those machines fro being damaged by the friction or compression of the ma rials contained in the hold, and particularly to prevent th ntrance of ballast, &c., by which the tubes would preser y be choked, and the pumps rendered incapable of servic By means of this enclosure, the artificers may likewi more readily descend into the hold in order to examine th tate of the pumps, and repair them as occasion requires.

ELLESLEY'S ISLANDS, a group of islands so called by aptain Flinders, at the head of the Gulf of Carpentaria, on he north coast of New Holland. Their names are M ington isle, Pisonia, Bentinck, Sweer's island, and seve other small and rocky islets.

ELLINGBOROUGH, a market-town of the county of orthampton, in the hundred of Hamfordshoe, sixty-eight mi s from London, and seven from Northampton, on the riv Nen. It is a well-built town, in which the making of bo s and shoes and bobbin lace is still carried on, though th latter trade has declined. Near to it are some medici springs, not now in request. From these the place de ved its name. There is a good market on Wednesday. Th population amounted in 1821 to 4454, and in 1831 to 4 3.

ELLINGTON, a market-town in the county of Som ect and hundred of West Kingsbury, on the river Tone, 15 miles from London and seven from Taunton. It is in a h district, is well built, has an ancient noble church, an a new one recently erected at the sole expense of the cl ryman. The town formerly had a considerable trade in m ing serges and other woollen goods, but that branch of in stry has greatly declined of late years. Some pottery wa is made. There is a well-frequented market on Thursda The population amounted in 1821 to 4170, and in 18 to 4762.

ELLINGTON, a market-town of the county of Salop, in e hundred of South Bradford, near the Wrekin, 150 m s from London. It is a well-built place, has a handso e church of modern erection, supported by cast-iron pi rs. There is a good market on Thursday, and very co iderable occupation afforded by the mines of iron and of al in the vicinity, and by some large iron furnaces. The po lation amounted in 1821 to 8390, and in 1831 to 9671.

ELLS, a city of the county of Somerset, in the hundr of Wellsforum, 120 miles from London and eighteen fr Bath. It is situated in a rich valley at the foot of th Mendip Hills, which supply abundance of coal. It is to ably well built, though many of the houses are of an an que fashion, whilst others of more modern erection ar very handsome. The streets are well paved, and rem kably clean. In conjunction with Bath, it is the seat of a shop, whose palace in the city is one of the best episcopa esidences in the kingdom. The cathedral is a spacious G hic structure in the form of a cross, 380 feet long and 1 feet wide. The most remarkable part of the building is e west front, which is most elaborately ornamented with st es of most excellent carved work in stone. One of th windows contains some beautiful paintings on glass. T chapter-house is remarkable for its structure in the fo of a rotunda, having its roof supported by a single pi r in the centre. The deanery is a handsome residence, and the houses of the vicars within the close are very commodious. Besides those belonging to the church, there are several other charitable establishments. Near the city is St Andrew's Well, whose water is conveyed by pipes to an elegant conduit near the market-cross, and from thence runs through a part of the city. The civil government is vested in the corporation, consisting of a mayor, four aldermen, and eleven councillors; and the city returns two members to the House of Commons. Besides the cathedral, is the parish church of St Cuthbert, with a lofty square tower, and a fine set of six bells; and various places of worship for dissenters. There are good markets on Wednesday and Saturday, and four annual fairs. There are horse-races yearly near the city. The population amounted in 1821 to 5888, and in 1831 to 6649.

WELLS, a market-town of the county of Norfolk, in the hundred of North Greenhoe, 118 miles from London. It stands on the shore of the German Ocean, has a small port and custom-house, but the trade is inconsiderable. The population, including that of the parish, which extends far beyond the town, amounted in 1821 to 2950, and in 1831 to 3624.

WELSHPOOL, a borough-town and parish of the county of Montgomery, in North Wales, in the hundred of Pool, 177 miles from London. It is pleasantly situated and well built, with a convenient county-hall, in which the assizes are held. It is near the river Severn, and is connected with it by a canal, and by another with Ellesmere. It is the chief place where the Welsh flannels are collected from the neighbouring peasantry. The corporation consists of four aldermen and twelve councillors, and the borough returns one member to the House of Commons. The population amounted in 1821 to 3535, and in 1831 to 3500.

WEM, a market-town and large parish of the county of Salop, in the hundred of North Bradford, 172 miles from London. It chiefly consists of one large street, with a few smaller. It has a very handsome church, a free school, and two dissenting chapels. There is a good market on Thursday, and three annual fairs. The population amounted in 1821 to 3621, and in 1831 to 3967; but this includes ten small townships, as Wem itself in 1831 contained only 1932 inhabitants.

WEMYSS, EASTER, a village, situated on the shores of the Firth of Forth, in the county of Fife. Its inhabitants, amounting in 1831 to 858, are principally weavers.

WEMYSS, *Wester*, a seaport town about a mile distant from the above. It consists almost entirely of one street, which is in good order, as is also the small harbour. The principal business is connected with the exportation of coals from the extensive coal-mines belonging to the family of Wemyss, which have been worked for many centuries, and now extend to a considerable distance under the sea. Weaving is also carried on by a few of the inhabitants. The population amounted in 1831 to 858.

WENDEN, a circle of the Russian government of Livonia, extending in north latitude from 56° 35′ to 57° 54′, and in east longitude from 25° 3′ to 27° 22′. It is bounded by Pernau on the north, by Dorpat on the east, on the south-east by Witebsk, and on the south-west and west by Riga. It comprehends 4158 square miles, with two cities, twenty-eight parishes, 229 hamlets and villages, and 136,400 inhabitants. It is generally a level district, with a few undulations, watered by many small streams, all of which end in the Duna. It produces some corn, chiefly rye or oats. The chief object of cultivation next to grain is flax, which, as well as the seed of that plant, is mostly exported from Riga. Some tallow and wood also furnish articles for foreign trade. The capital is the town of the same name on the river Aa. It was once the assembling place of the knights of the Teutonic order, and many of their monuments still exist in the church. Long. 25. 10. E. Lat. 57. 15. N.

WENDOVER, a borough and market town of the county of Buckingham, in the hundred of Aylesbury, thirty-five miles from London. It is a poor place, with little or no trade except what is connected with lace-making. It returned two members to the House of Commons till 1832, when it was disfranchised. A small market is held on Thursday. The population amounted in 1821 to 1602, and in 1831 to 1927.

WENEW, a circle of the Russian province of Tula, extending in north latitude from 54° 20′ to 55° 50′, and in east longitude from 37° 39′ to 38° 34′. It contains one city, 147 villages, besides the establishments of some nobles, and 25,500 inhabitants. It is watered by the rivers Oker and Wenewka. The land is moderately fertile, and but in a small part covered with woods. The capital is a city of the same name on the Wenewka, containing 790 houses, with 3400 inhabitants. It is 625 miles from St Petersburg. Long. 38. 1. E. Lat. 54. 20. N.

WENLOCK (called either MUCH or GREAT WENLOCK), a borough and market town of the county of Salop, in the division called the Franchise of Wenlock, 151 miles from London. It is a very ancient town, but very ill built. It is said to have been the first town that sent members to parliament in 1478, but it was not incorporated till the reign of Charles the First. It has now six aldermen and eighteen councillors, and sends two members to the House of Commons. It is a place of but little trade, and that only on the market of Friday. The population amounted in 1821 to 3165, and in 1831 to 3481.

WEOBLY, a market-town of the county of Hereford, in the hundred of Stretford, 146 miles from London and twenty-one from the city of Hereford. It is a place of considerable antiquity, and consists of one principal street with well-built houses. It has a market on Thursday. There are two good charity schools. The population amounted in 1821 to 739, and in 1831 to 819.

WERAD, a town of Hindustan, in the Mahratta territories, in the province of Bejapoor, sixty-three miles south-south-west from Poonah. Long. 73. 48. E. Lat. 17. 30. N.

WERCHNE-DNIAPROWSK, a circle of the Russian government of Jekaterinoslaw. It extends in north latitude from 51° 8′ to 52° 7′, and in east longitude from 33° 45′ to 34° 57′. The land is very fertile, and repays with good interest whatever industry is expended on it. It breeds many valuable herds of horned cattle, as well as sheep. The Dnieper touches the circle on the north-east, and there receives the waters of many small streams. The population is thin, but is not precisely known, as a portion consists of Kossacs, whose residence is not permanent, and some of them are colonists from Poland and Germany, recently established. The capital is the city of the same name on the right bank of the Dnieper, lately founded, and said to contain yet not more than 1500 inhabitants. It is 1066 miles from St Petersburg. Long. 34. 41. E. Lat. 51. 8. N.

WEREJA, a circle of the Russian government of Moscow, extending in north latitude from 53° 27′ to 54° 19′, and in east longitude from 37° 30′ to 37° 47′. It is bounded on the north by Mohaisk, on the north-east by Swenigorod, on the east by Podol, on the south by Kaluga, and on the west by Smolensko. It comprehends 654 square miles, with one city, 234 large villages, and 66,450 inhabitants. The surface is undulating, the soil rather sandy, with some marshes, and is well watered with several small streams. A great part of the circle is covered with fir woods. The capital is the city of the same name on the river Protwa, which divides it into two parts, and is navigable for small craft. It is fortified, but not strongly; has two wooden and two stone churches, 820 houses, and 7300 inhabitants, who carry on trade largely in the productions of the circle. It is 480 miles from St Petersburg. Long. 35. 55. E. Lat. 55. 29. N.

WERNIGERODE, a principality in Prussia, now mediatised, and forming a portion of the circle of Osterwick, in the province of Saxony. The family of Stolberg-Wernigerode were formerly the sovereigns, and are now the proprietors, and in a secondary sense the governors, having the patronage of all clerical, civil, and judicial offices, and the power of pardoning smaller offences, as well as of granting dispensations respecting marriages and the game-laws. The principality, which includes a part of the Hartz Forest, with the Brocken, is about 101 square miles in extent, comprehending one city, one market-town, eleven villages, and many hamlets and detached farms, with 1530 houses, and 14,640 inhabitants. The capital, of the same name, is situated at the foot of the Hartz Mountains, on a small stream called the Zillerbach, but is 820 feet above the level of the sea. It includes the residence of the court, in a fine situation, with a library of more than 30,000 volumes. The town is irregularly and ill built, but is surrounded with walls. It contains four churches, an orphan-house, a poor-house, a gymnasium, and 870 dwellings, with 5340 inhabitants, who carry on some trade in linens, in paper, in copper, and in distillation, but depend much on the residence of the court, and on the numerous summer visitants to the Hartz. It is in longitude 10. 47. 35. E. and latitude 51. 50. 34. N.

WERREAR, a district of Hindustan, on the north-west frontier of the province of Gujerat, extending along the banks of the Banass river. This country is famed for its excellent grass, to which it is indebted for its name, Wuddyar or Wandyar signifying in the Gujerattee language a herdsman; and is resorted to by immense herds of cattle sent to pasture on the banks of the Runn. Sheep are cheap and abundant, and it produces also horses of a smaller breed than those of Cottiwar; but few are exported, those of a good quality being in great demand. The district is much infested by plundering Coolees, the principal haunts of these robbers being at Warye, fourteen miles south-west from Rahdunpoor, Barbere, twenty-four miles north, and Therwara, thirty miles north-west from Rahdunpoor, the latter possessed by the Balooches.

WERTURIAN or URALIAN MOUNTAINS. See OURAL MOUNTAINS.

WESEL BAY, on the south coast of the island of Java. Long. 113. 42. E. Lat. 8. 21. S.

WESENBERG, a circle in the Russian province of Esthonia, formerly called Wierland. It extends in north latitude from 58° 45′ to 59° 40′, and in east longitude from 25° 40′ to 28° 3′, and comprehends 1910 square miles, with two towns, seven parishes, and 157 hamlets, in which are seventeen Lutheran and one Greek church, with 49,850 inhabitants. It stands on the shore of the Gulf of Finland, and is well watered by several streams. It contains many morasses, and much woodland. The capital is a town of the same name on the river Soli. It has little trade, and the chief occupation is in the river and sea fishery. Long. 26. 18. E. Lat. 59. 28. N.

WESLEY, JOHN, founder of the sect of Methodists, was the son of Samuel Wesley, rector of Epworth, in the isle of Axholme in Lincolnshire, and was born in that village in the year 1703. His very infancy was distinguished by an extraordinary incident; for when he was only six years old, the parsonage-house at Epworth was burnt to the ground, and the flames had spread with such rapidity that few things of value could be saved. His mother, in a letter to her son, Samuel Wesley, then on the foundation at Westminster school, thanks God that no lives were lost, although for some time they gave up *Poor Jacky*, as she expresses herself; for his father had twice attempted to rescue the child, but was beaten back by the flames. Finding all his efforts ineffectual, he resigned him to divine providence. But parental tenderness prevailed over human fears, and Mr Wesley once more attempted to save his child. By some means equally unexpected and unaccountable, the boy got round to a window in the front of the house, and was taken out by one man's leaping on the shoulders of another, and thus getting within his reach. Immediately on his rescue from this very perilous situation, the roof fell in. This extraordinary escape explains a certain device, in a print of John Wesley, engraved by Vertue in the year 1745, from a painting by Williams. It represents a house in flames, with this motto from the prophet, "Is he not a brand plucked out of the burning?" Many have supposed this device to be merely emblematical of his spiritual deliverance; but from this circumstance it is apparent that it has a primary as well as a secondary meaning; it is real as well as allusive.

In the year 1713 he was entered a scholar at the Charterhouse in London, where he continued seven years under the tuition of Dr Walker, and of the Rev. Andrew Tooke, author of the Pantheon. In his seventeenth year he was sent to Christ Church at Oxford. In 1726 he was elected a fellow of Lincoln College, and took the degree of A. M. in 1727. He was afterwards appointed a tutor of his college. He discovered very early an elegant turn for poetry. Some of his gayer poetical effusions are proofs of a lively fancy and a fine classical taste; and some translations from the Latin poets, while at college, are allowed to have great merit. He had early a strong impression, like Count Zinzendorf, of his designation to some extraordinary work. This impression received additional force from some domestic incidents, all which his active fancy turned to his own account. His wonderful preservation, already noticed, naturally tended to cherish the idea of his being designed by Providence to accomplish some purpose or other that was out of the ordinary course of human events.

The reading of the writings of Mr William Law, the celebrated author of Christian Perfection, and of a Serious Address to the Christian World, contributed to lead John Wesley and his brother Charles, with a few of their young fellow-students, into a more than common strictness of religious life. They received the sacrament of the Lord's Supper every week, observed all the fasts of the church, visited the prisons, rose at four in the morning, and refrained from all amusements. From the exact method in which they disposed of every hour, they acquired the appellation of *Methodists;* by which their followers have been ever since distinguished.

From Dr Potter, bishop of Oxford, he received deacon's orders in 1725, and priest's in 1728. For some time he officiated as his father's curate. But the boundaries of this island were soon deemed by Wesley too confined for a zeal which displayed the piety of an apostle, and of an intrepidity to which few missionaries had been superior. In 1735 he embarked for Georgia, one of our colonies, which was at that time in a state of political infancy; and the great object of his voyage was to preach the gospel to the Indian nations in the vicinity of that province. He returned to England in 1737. Of his spiritual labours, both in this country and in America, he himself has given a very copious account, in a series of Journals printed at different periods. These journals drew upon our laborious preacher and his coadjutors some severe animadversions from two prelates, Dr Lavington, bishop of Exeter, and Dr Warburton, bishop of Gloucester. The former published, in three parts, the Enthusiasm of the Methodists and Papists compared; the third part of this performance containing a personal charge of immoral conduct. Mr Wesley, in his vindication, published a letter to his lordship, which produced a reply from the latter. Bishop Warburton's attack is contained in his celebrated treatise, entitled "The Doctrine of Grace: or, the Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity, and the Abuses of Fanaticism: concluding with some thoughts, humbly offered to the consideration of the Established Clergy, with regard to the right Method of defending Religion against the Attacks of either party." Lond. 1762, 2 vols. 8vo. There is much acute reasoning, and much poignant and sprightly wit, in his Doctrine of Grace; but there is too much levity in it for a grave bishop, and too much abuse for a candid Christian. On this occasion Wesley published a letter to the bishop, in which, with great temper and moderation, as well as with great ingenuity and address, he endeavoured to shelter himself from his lordship's attacks, not only under the authority of the holy Scriptures, but of the church itself as by law established.

On his return from Georgia, Mr Wesley paid a visit to Count Zinzendorf, the celebrated founder of the sect of Moravians or Hernhutters, at Hernhut in Upper Lusatia. In the following year he appeared again in England, and with his brother Charles, at the head of the Methodists. He preached his first field sermon at Bristol, on the 2d of April 1738, from which time his disciples have continued to increase. In 1741 a serious altercation took place between him and Whitefield. In 1744, attempting to preach at an inn at Taunton, he was regularly silenced by the magistrates. Although he chiefly resided for the remainder of his life in the metropolis, he occasionally travelled through every part of Great Britain and Ireland, establishing congregations in each kingdom. In 1750 he married a lady, from whom he was afterwards separated. By this lady, who died in 1781, he had no children. He had been gradually declining for three years before his death; yet he still rose at four in the morning, and preached, and travelled, and wrote as usual. He preached at Leatherhead in Surrey, on the Wednesday before that event. On the Friday following, appeared the first symptoms of his approaching dissolution. The four succeeding days he spent in praising God; and he left this scene, at a quarter before ten in the morning of the 2d of March 1791, in the 88th year of his age. His remains, after lying in a kind of state at his chapel in the City Road, dressed in the sacerdotal robes which he usually wore, and on his head the old clerical cap, a Bible in one hand, and a white handkerchief in the other, were, agreeably to his own directions, and after the manner of the interment of Mr Whitefield, deposited in the cemetery behind his chapel, on the morning of the 9th March, amid an innumerable concourse of his friends and admirers, many of whom appeared in deep mourning on the occasion.

Wesley was a very various and voluminous writer. Divinity, both devotional and controversial, biography, history, philosophy, politics, and poetry, were all, at different times, the subjects of his pen; and whatever opinion may be entertained of his theological sentiments, it is impossible to deny him the merit of having done very extensive good among the lower classes of people. He certainly possessed great abilities, and a fluency which was well accommodated to his hearers, and highly acceptable to them.

WESSEL'S ISLANDS, a chain of islands which extends north-eastward from the north coast of New Holland, thirteen leagues, at the entrance of the Gulf of Carpentaria, on the west side. The inhabitants are barbarous in the extreme, and go about naked. The northern extremity is in lat. 11. 18. S.

WEST, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined the intersection of the prime vertical with the horizon on that side the sun sets in.

WEST, *Gilbert*, was the son of Dr West, prebendary of Winchester, who published an edition of Pindar in 1697. He studied at Winchester and Eton, and from thence was placed in Christ Church, Oxford. His studious and serious turn inclined him to take orders; but Lord Cobham, his maternal uncle, diverted him from that pursuit, and gave him a cornetcy in his own regiment. This profession he soon quitted on account of an opening of another nature, which presented him with a flattering prospect of advancement in life. A number of young gentlemen were to be selected from the universities, and, at the expense of government, were to be taught foreign languages, and then sent to the secretary's office, to be initiated into business, and trained there for the public service, as envoys, ambassadors, &c. West was one of the few pitched upon; and on his first introduction into that office, Lord Townshend, secretary of state, treated him with singular marks of regard, and the strongest inclinations to serve him were testified from all quarters. But Lord Cobham's strong opposition to the measures of the government rendered these advantages entirely fruitless; and the ministers honestly told Mr West that he must not expect them to distinguish his merit, as any favours conferred upon him would be imputed as done to his uncle. He now left that office, and all his views of making his fortune; and entering into the married state, retired to Wickham in Kent, where he lived in great domestic comfort and tranquil happiness. He was there visited by his valuable friends, who held the most delightful converse of wit, humour, and learning, supported upon the principles of virtue, sound reasoning, and solid friendship, which rendered the whole cheerful, animating, and instructive. In 1752 he was appointed one of the clerks of the privy council; and Pitt, on becoming paymaster, nominated him treasurer of Chelsea Hospital. Towards the end of his life, he wholly applied himself to the study of the Scriptures, being extremely anxious to try his utmost endeavours to reconcile the seeming inconsistencies which gave the enemies of revealed religion a handle to doubt and discredit their authenticity. The result of his inquiries was partly communicated to the public in his "Observations on the Resurrection." Lond. 1747, 8vo. This work procured him from the university of Oxford the degree of LL. D. conferred by diploma. On the evidences of the truth of the New Testament he meditated another work, but did not live to execute his design. He lost his only son in 1755; and on the 26th of March in the following year, a stroke of palsy terminated his own career. He left behind him the character of an amiable and pious man. His Observations, which, it has been said, were written to confirm the wavering faith of his great friends Pitt and Lyttelton, bear ample testimony to his reasoning powers and the sincerity of his religion, while his translations from Pindar shew him to have been a respectable Greek scholar, and very considerable poet. His "Dissertation on the Olympick Games" is likewise a creditable specimen of his learning.

West Island, one of the smaller Philippine islands, near the south coast of Mindoro. Long. 121. 12. E. Lat. 12. 15. N.

West Island, a small island at the east entrance of the Straits of Sunda. Long. 196. 20. E. Lat. 5. 27. S.

West Island, a small island in the Eastern Seas, near the south coast of Cumbava. Long. 119. 2. E. Lat. 8. 49. S. Another island on the north coast of New Holland, near the head of the Gulf of Carpentaria, about ten miles long and five broad. It is one of the three called by Captain Flinders Sir Edward Pellew's group.

WEST-BROMWICH, a parish of the county of Stafford, in the hundred of Offlow, 122 miles from London. It is a very scattered place, and affords considerable occupation in various branches of the iron manufacture. Besides the old parish church, two others have been recently erected. The population amounted in 1821 to 9505, and in 1831 to 15,327.

WESTBURY, a borough of the county of Wilts, in the hundred of its own name, ninety-seven miles from London. There is a church of Gothic architecture, and a town-hall, and it has a market on Thursday. The chief trade consists in making fine woollen cloths and cassimeres. It returns one member to the House of Commons. The population amounted in 1821 to 6846, and in 1831 to 7324.

WESTERAS, an internal province of the kingdom of Sweden, formed out of a small portion of the ancient province of Upland, and the eastern part of Westmanland. It is now bounded on the north-west by Kopparberg, on the north-east by Gefleborg, on the east by Upsala, on the south by Malaren and Nykoping, and on the west by Orebro. It extends over 2772 square miles, and comprehends four cities and 2818 villages and hamlets, with 87,600 inhabitants. It is a well-watered district, and, for the climate, very fruitful, but chiefly consisting of pasture-land, and consequently rendered profitable more by its dairies and by fattening cattle than by its ploughed fields. It generally, however, grows corn sufficient for its consumption, and in very favourable years has a surplus. The fisheries are productive; but the chief demand for labour is in the mines and in their products. The silver-mine of Sala is still worked, being the only one now in Sweden; and the iron-mines of Norberg yield the best quality of metal. The exports are wood, cattle, silver, iron, and cutlery goods, and in some years corn. The province, for the purposes of government and law, is divided into seven bailiwicks. The capital is the city of the same name, at the mouth of the river Swartelf. It is the seat of a bishop, and is finely situated, but irregularly built. In the cathedral are monuments of two of their kings, Gustavus III. and Erick XIV. There is a gymnasium, with nine professors, and an hospital. It contains 570 houses, chiefly built of wood, and 3120 inhabitants. It has some trade by the Malaren Lake, chiefly with Stockholm. Long. 16. 22. 28. E. Lat. 59. 35. 31. N.

WESTERHAM, a market-town of the county of Kent, in the lathe of Sutton, and the hundred of the same name, twenty-two miles from London. It is on the borders of Surrey, is pleasantly situated and neatly built, with some very good houses. The market-house, though small, is an elegant building. The church contains a monument to General Wolfe, who was a native of this place. There is a market on Wednesday for corn. The population amounted in 1821 to 1742, and in 1831 to 1926.

WESTMEATH, an inland county in the province of Leinster, in Ireland, is bounded on the north by Longford and Meath, on the east by Meath and Kildare, on the south by the King's county, and on the west by Roscommon. It lies between 53° 20′ and 53° 47′ N. lat., and 7° and 7° 55′ W. long., extending forty miles in its greatest length from north to south, and forty-five in its greatest breadth from west to east, and comprehending an area of 708 square miles, or 453,468 acres, of which 431,041 are land, and the remaining 22,427 are covered with water. It ranks as the twenty-sixth county in superficial extent, and the twenty-fourth in that of its cultivated land.

The county originally formed part of the central kingdom of Meath, when it was distinguished by the name of Eircamhoin, or the western division. Nor was it till the reign of Henry VIII. that it was formed into a separate county, including within it the district of Longford, which continued to form part of it till the reign of Elizabeth. Before the English invasion, the M'Geoghegans, chieftains of Moycashel, the Malones, and the Magardleys, were the principal families. When the palatinate of Meath was granted to Hugh de Lacy by Henry II., the former proprietors were supplanted by English settlers, the principal of whom were the families of Petit, Tuite, Hussey, Dalton, Delamaine, Nugent, Geneville, Nangle, Ledwich, and Constantine. The confiscations consequent on the wars of 1641 and 1688, in both of which the landed gentry took an active part, made very great alterations in the state of property. The landing of a French force in the west of Ireland in 1798 occasioned a partial insurrection in this county, in the course of which the armed peasantry seized and fortified Wilson's Hospital, but were quickly dispossessed of it by a detachment of the royal forces.

This district forms the most elevated portion of the great central plain of Ireland, which is here 274 feet above the sea-level; but no part of it is mountainous. The highest elevations are Knocklayde in the north, 795 feet high, and the Hill of Ben, 710. All the hills are suited, even to their summit, for pasturage, and some for tillage; many are richly clothed with timber. Lakes are numerous: the largest lie in a direction nearly north and south along the middle of the county. Lough Shillin, the most northern, is a border lake on the side of Cavan, and near it is the smaller border lake of Lough Kinnail or Kinully. Lough Dereveragh is a winding expanse of water, eleven miles long and three broad, bordered in some parts by steep hills richly clothed with trees. Farther south is Lough Owell or Hoyle, studded with islands, and Lough Tron or Hiern, of smaller dimensions. The most southern, and also the largest lake of the chain, is Lough Ennell, equally admirable for its scenic beauties and for its extent of surface. A number of smaller lakes are scattered throughout the county. Loughs Lene, Bawn, Glyde, and Fore, are in the northern part; the small but romantic lake of Loughsewdy in the western. Lough Drin is remarkable only for its great depth; it covers but an acre of land. Lough Ree or Reagh, which is in reality a portion of the Shannon, forms part of the western boundary of the county, separating it from that of Roscommon. It is twenty miles in length, and contains several islands, two of which were the sites of religious foundations.

Though no large rivers traverse this portion of the island, it may be considered to be the source of several. The Inny, which rises in Lough Ramor in Cavan, and enters Westmeath through Lough Shillin, through the most part of its course forms the boundary line on the side of Longford, but in one part traverses the county, and after dividing two of its baronies, ultimately joins the Shannon. Two small rivers, the Golden and Silver Arms, which issued from the northern and southern extremities of Lough Owell, have been closed up, so as to increase the quantity of water in the parent lake, which is the main feeder of the Royal Canal. The Brosna flows from Lough Ennell into the Shannon, which forms part of the western boundary of the county. Lough Lene also gives rise to two streams of some notoriety. The northern, after sinking into the ground near the village of Fore, and re-appearing, empties itself, under the name of the Glore, into the Inny, and the united streams pass through the Shannon into the Atlantic. The southern forms the Deel, which joins the Boyne, and falls into the Irish Sea. Hence this little lake, with its two perennial branches, may be said to divide Ireland into two islands.

The county forms part of the great limestone field that traverses the island across its centre. This substratum is interrupted in two places only, the one at Moat-a-Grenogue, and the other near Ballymahon, at each of which places the sandstone rises from under the limestone bed, and forms insulated protuberances of some elevation. In some places the limestone is wrought up for architectural and domestic purposes, but in others its quality is such as to render it nearly unfit for the farmer's use, in consequence of the quantity of fuel required for its calcination. Traces of lead and copper have been discovered, but not in quantities sufficient to hold out a fair prospect of pecuniary remuneration by exploring them farther. Coal is also said to have been raised in small quantities. A chalybeate spring rises at Grangemore, near Kinnegad, bursting forth with force, and forming a copious stream; but in consequence of the difficulty of access to it, few take advantage of its medicinal virtues. The soil is in general a deep rich loam resting on the limestone, but in the flat lands in the west it is light. The centre is intersected with numerous eskers formed of calcareous gravel. There is much bog: that of Allen covers a large portion of the western baronies. Many parts are well timbered; and traces of the old forests show themselves by the spontaneous growth of indigenous trees of various kinds in places where the young shoots are protected from the depredations of cattle.

The progress of the population, and its actual state, according to the latest census, appear in the following table.

Year.	Authority.	No.
1760	De Burgo	50,340
1792	Beaufort	69,000
1812	Parliamentary census	112,000
1821	Ditto	128,819
1831	Ditto	148,161

The last of these returns gives a population of one inhabitant to every 3·06 acres. The return of the Commissioners of Public Instruction in 1834, taken according to dioceses, gives a population to the county of about 138,560 souls, of whom 10,175 are of the established church, 251 Protestant dissenters, and 128,133 Roman Catholics. The number of children receiving instruction in the public schools, at the periods stated beneath, is as follows, according to returns made to parliament.

	Boys.	Girls.	Sex not ascertained.	Total.
1821	4952	2374	—	7326
1824–6	5740	3820	359	9919
1836–7	1717	1656	—	3373
1837–8	1881	1664	—	3545
1838–9	2126	1925	—	4051

According to the return of 1824-6, the number of Catholic children educated in the public schools was 8249, of Protestants 1533, and of dissenters six; that of those whose religious persuasion could not be ascertained amounting to 131. The total number of schools was 216, out of which number twenty-six, containing 1532 pupils, were maintained wholly by grants of public money; twenty-five, with 1542 pupils, by voluntary subscriptions; all the remaining schools, in number 165, and educating 6845 children, being supported wholly by the fees of the pupils. An establishment for the maintenance and education of 160 boys, the sons of Protestant parents, natives of Westmeath, who are afterwards apprenticed to Protestant artificers, with a fee of L.10 each, was founded under the will of Andrew Wilson of Piercefield, Esq. and still exists. The estate bequeathed for this purpose amounts to L.4000 per annum. Under the incorporated society for erecting charter schools, there is a school situate at Leney, six miles from Mullingar, intended for the maintenance and education of sixty children.

The county is divided into the twelve baronies of Brawney, called also the territory of Brawney, Clonlonan, Corkaree, Delvin, Demifore, Farbill, Fartullagh, Kilkenny-west, Moyashel and Magheradernon, Moycashel, Moygoish, and Rathconrath. These are subdivided into sixty-two parishes, of which fifty-nine are in the diocese of Meath, and three in that of Ardagh. It was represented in the Irish parliament by ten members, two for the county, and two for each of the boroughs of Athlone, Fore, Kilbeggan, and Mullingar. By the arrangements under the union act, all the boroughs were disfranchised, except the first, which belongs only partially to this county, one half of it being in Roscommon; it now returns one member. The constituency for the county was as follows in the under-named years.

Date.	No.	Date.	No.	Date.	No.
1829	2601	1833	1395	1837	1525
1830	641	1834	1395	1838	1525
1831	921	1835	1395	1839	1300
1832	1395	1836	1526		

The number of electors in the last of these returns gives an average of one elector to every 106 individuals, or of one to every eighteen heads of families of six individuals each.

The county is in the home circuit. The assizes are held at Mullingar. General sessions of the peace are held alternately in that town and in Moate. The local government consists of a lieutenant, fifteen deputy-lieutenants, sixty-nine unpaid magistrates, and a stipendiary, under whom there is a constabulary force, consisting of a county inspector, six sub-inspectors, seven head constables, and 272 constables and sub-constables. The county infirmary is in Mullingar, a fever hospital at Castlepollard, and fifteen dispensaries in various places. Lunatics are sent to the district asylum at Maryborough, where forty patients from the county are received. Mullingar and Athlone have been fixed on as sites for the workhouses of poor-law unions.

All kinds of grain thrive well in this productive soil. The English system of tillage is adopted by all except the poorer farmers and cottagers. Wheat forms a part of every succession of crops, and green crops are very frequent. Limestone gravel, which is to be had in abundance in most parts, is the usual manure. The fences are bad, except in the demesnes of the gentry. The low lands and valleys produce abundance of rich grass; from which cause, and as the management of cattle has been found more profitable and less laborious than tillage, most of the land in the county is assigned to the former department of rural economy. Great attention is paid to the breeds of cattle, which, both great and small, are purchased chiefly at the fairs of Ballinasloe. The long-horned cows are preferred, as being large, and good milkers. The breed of horses is excellent. Many are brought young from Connaught, and reared here till fit for the market. Dairies are frequent, and butter is made in large quantities. The method of haymaking is bad, the hay being allowed to stand in small stacks in the field till late in the season, in consequence of which it is much injured both by the heat and the rains. Like most other parts of the island, timber was abundant, until destroyed by a lavish and improvident use of it, which made no provision for a fresh supply. The deficiency is severely felt; but here, as elsewhere, great exertions are making to remedy it by young plantations, which are now rising in many parts.

The manufactures are not, nor were they ever, of any magnitude; the making of woollen and linen cloths being almost wholly confined to the domestic demand, and the operations carried on in the farmers' houses. Fish is abundant in the lakes and rivers. Bream, trout, pike, and eels, are taken in the Inny; salmon in the same river and in the Brosna. The goaske, a fish about the size of the herring, is found in Lough Dereveragh; a thin-shelled mussel in some of the bogs. The Royal Canal passes through the central part of the county from east to west; a branch of the Grand Canal proceeds from near Philipstown in King's county to Kilbeggan. There are three banking establishments, one a branch of the Provincial, the other two of the National Bank of Ireland. There are nine loan societies, in which the total amount of the loans in the hands of borrowers at the close of 1839 was L.10,675, and the total number of borrowers during the year 9071. Under the direction of the late Commissioners for Railroads in Ireland, a survey has been made of a line from Dublin, to enter the county near Killucan, and to proceed to Mullingar, whence it is to diverge in two branches, the one north-west through Longford to Sligo, the other westward through Athlone to Galway; but no steps have yet been taken to carry the plan into execution.

A considerable number of the landed proprietors reside on their own property; hence the county contains many elegant mansions and villas, surrounded by well-planted demesnes, which add very much to the natural beauties of the landscape. In the demesne of Mount d'Alton is an obelisk fifty feet high, erected in honour of the empress Maria Theresa, the Emperor Joseph, and King George III., by a late member of the D'Alton family, a retired officer in the Austrian service. An obelisk of similar dimensions stands on the estate of Lowville, near Kilkenny-west. The character of the middling and lower classes is superior to that of those in the adjoining county of Meath. The peasantry are described as being lively, intelligent, and quick-witted; hasty in their tempers, and prone to litigation; unwilling to deviate from the habits and customs of their forefathers; lax in their ideas of morality towards their superiors, but rigidly observant of the engagements voluntarily entered into with one another, and of the religious observances imposed on them by their clergy. They are also much addicted to superstitious practices. The horses are bathed in one of the lakes on the second Sunday in August, called Garlic Sunday, from a belief that they will thus be secured from injury during the rest of the year. Fish taken out of the stream that sinks into the ground near Fore will not be eaten, in consequence of the religious respect with which the water of it is honoured. A disinclination to improvement in their farms, and to domestic neatness, is also observable. The cottages are ill constructed and badly furnished, the roofs being made of boughs of trees with the leaves on, covered with sods of turf or peat called scraws, and thatched with straw. Many are without chimneys, the place of which is supplied by a hole in the roof. The furniture consists of a deal table, a few stools, an iron pot, and a dresser, with a few plates and dairy utensils. Yet their clothing is comfortable, usually of home-made gray or drab frieze. The use of linen has of late been almost universally superseded by cotton. The favourite garment of the men is a large loose coat, wrapped up in which they go to the fairs and markets even during the heat of summer, followed by their wives, who transact most of the business there. The women spin the wool and flax for their clothing, perform the household work, and take a large share in the labours of the field. When married, they still retain their maiden names. English and Irish are spoken, but the use of the latter is more general in their intercourse with one another.

Many remains of antiquity still exist. The parish of Rathconrath takes its name from a rath or moat of large dimensions and peculiar construction; besides which, nine of smaller size have been discovered within its boundaries. A still more remarkable pile of the same kind exists at Ballymore. It had originally been a Danish fort, and its position was so well chosen for military purposes, that it was strongly fortified by the Irish in the wars of 1641 and 1688; and after its capture by the English in the latter period, it was made the head-quarters of General Ginckell when preparing to besiege Athlone. A third, called the Fort of Turgesius, as being the reputed place of residence of that monarch during his reign in Ireland, is to be seen near Lough Lene. Those of inferior note are too numerous to be particularized. The ruins of ancient castles are also visible in many places. The origin of several of them can be traced back to Hugh de Lacy, the first lord palatine of the county. His chief place of residence was at Kilbixy, where he had a large and well-fortified castle, and where also stood a town of such importance as to be governed by a mayor or sovereign, and burgesses, with their usual appendages of inferior officers. The site of the former is now merely matter of conjecture; and the privileges, and consequently the importance, of the latter have been transferred to Mullingar. Another of this nobleman's castles was at Ardnurcher, better known by the name of Horseleap, from the romantic tradition of an extraordinary bound made by a horse across a cleft between two steep hills, in effecting which the animal is said to have left the marks of its hoofs on the rock whence it started, and their traces are supposed to be visible to the present day; or from a leap over the drawbridge, made by a knight in effecting his escape from the castle. The castle is also noted in history as being the place where the same De Lacy was treacherously killed by one of his own menials. The castles of Sonnagh, Rathwire, and Killare, were built by the same nobleman. In the barony of Moycashel are the remains of several castles formerly possessed by the M'Geoghegans, the ancient proprietors of the soil. Some of the old monastic buildings have been converted into parochial places of worship, both Protestant and Roman Catholic. The ruins of a few are still in existence, but the locality of many others is now a subject tending rather to excite than to satisfy curiosity. The ruins of Tristernagh Abbey, called also the Priory of Kilbixy, and founded by one of Hugh de Lacy's immediate successors, were visible till the year 1783, when they were totally destroyed. Near them are the remains of the chapel of Templecross, which, though of inferior note as a structure of monastic celebrity, is memorable from being the place where the corp-naomh, or blessed body, a relic of extraordinary sanctity, was found. The relic consists of a wooden box about the size of a small Bible, clasped with bands of brass, studded with valuable stones, and marked with a crucifix. Its contents, if any, are unknown, for no hand has yet been found of nerve sufficient to venture to force it open. It is used as a test of evidence. An oath on the corp-naomh is considered as an act of peculiar solemnity; a pledge which, if given in support of a falsehood, is supposed to bring down on the guilty person some visitation of dreadful consequence. Such is the respect paid even to its name, that if any one asserts what he wishes to be received with implicit credit, he avers its truth "by the corp-naomh that arose at Templecross." The site of the Abbey of Multifernan can still be traced by its ruins. It lies about four miles north of Tristernagh, and is singularly remarkable as being in possession of the Franciscan friars till the commencement of the year 1641, notwithstanding the total suppression of the monasteries by Henry VIII. upwards of a century before. For some years previous to the breaking out of the civil wars at the above-mentioned period, it had been much frequented by visitors of every description, who went thither, as was said, to arrange the plans of the ensuing insurrection. The unusual assemblage of strangers is also said to have excited such apprehensions in the mind of the then bishop of Ardagh, that he removed with all his property to England, and thus escaped the calamities with which so many who continued to reside in the country were visited. There were three religious houses at Mullingar, belonging respectively to the Dominicans, Franciscans, and Augustinians. At Kilkenny-west are the reliques of a preceptory of the Knights of St John. It is also remarkable for a noted holy well.

The population of Westmeath is so exclusively rural, that Mullingar, where the assizes are held, is the only town containing more than 2000 inhabitants. It is situate nearly in the centre of the county and of Ireland, at the junction of the barony of Fertullagh with that of Moyashel and Magheradernon, on the stream of the Golden Arm, about midway between Loughs Owell and Ennell. It was one of the ancient palatinate towns of the county, and suffered much by the ravages committed during the petty wars with the Irish. In the war of 1688, it was fortified by General Ginckell, and was for some time the head-quarters of the English army. Though it obtained a charter, it enjoyed none of the usual corporate rights, except that of returning two members to parliament, a privilege of which its proprietor or patron availed himself till the union. Four general sessions of the peace are held here. It is the site of the county court-house, prison, and infirmary, and has a large church, and a Roman Catholic chapel capable of holding 6000 persons, which is considered to be the cathedral of the diocese; the parish, with two others and a part of a third, being the mensal of the bishop, who resides in the town. The vicinity of the Royal Canal, which passes close to the northern side of the town, and on which steamers ply regularly to Shannon harbour, has made the place the centre of an increasing inland trade, which is also aided by the mail-road to Sligo passing through it. It holds a weekly market, and four fairs during the year. Large quantities of butter are brought to the former, and the latter are great marts for wool, horned cattle, and pigs; the November fair is for horses. One half of the town of Athlone is in this county, and is connected with the other half, lying on the Roscommon side, by a long bridge over the Shannon, so narrow that two carriages can with difficulty pass each other; but this check upon the communication between the two provinces of Leinster and Connaught is about to be obviated by the erection of a new bridge. The town is governed by a sovereign, two bailifs, and a recorder. It returned two members to the Irish parliament, and since the union one to the imperial parliament. The number of electors in 1832 was 243; in 1834, 274; and in 1839, 275. It is a place of great antiquity, being known as such before the settlement of the English; and after their arrival a castle was erected here by King John, to secure the main pass of the Shannon, which was deemed of such importance, that in a grant of the whole of Ireland by Henry III. to his son Edward, Athlone was specially excepted. It afterwards was the seat of government for the lord president of Connaught. In the war of 1642 it was taken by the Irish after a stubborn and protracted resistance, but subsequently retaken by the parliamentary army. In the war of 1688 it was invested by King William's forces under General Douglas, who was forced to raise the siege by means of the gallant defence of Colonel Grace; but it was soon after taken by storm by General Ginckell, in the face of the Irish army commanded by St Ruth. In 1697, the magazine was struck by lightning, and the castle and town nearly destroyed. It is still considered of such importance in a military point of view, that large works have been thrown up on its western side, in which a garrison is maintained. The population of Mullingar amounted in 1831 to 4295, that of the eastern portion of Athlone to 5655. The population of the other towns whose number of inhabitants exceed 1000 each is, Kilbeggan, 1985; Moate, 1785; Castlepollard, 1618. (C. P.)

Westminster.

WESTMINSTER, a city which forms the west part of the capital of Britain, but has a government distinct from the rest. This city had its name from the situation of its abbey, anciently called a *minster*, in respect of that of St Paul. That part properly called the city of Westminster, comprehending the parishes of St John and St Margaret, was once an island formed by the Thames, called *Thorney Island*, from the thorns with which it was overrun; and the abbey that stood in it, Thorney Abbey. The liberties of Westminster contain the several parishes of St Martin in the Fields, St James's, St Anne, St Paul, Covent Garden, St Mary le Strand, St Clement Danes, St George, Hanover Square, and the precinct of the Savoy. The government, both of the city and liberties, is under the jurisdiction of the dean and chapter of Westminster, in civil as well as ecclesiastical affairs; and their authority extends to the precinct of St Martin le Grand, by Newgate Street, and to some towns of Essex, which are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury; but the management of the civil part has, ever since the Reformation, been in the hands of laymen, elected from time to time, and confirmed by the dean and chapter. The chief of these laymen are the high steward, the deputy-steward, and the high bailif, who hold their offices for life.

West-moreland.

There are also sixteen burgesses and their assistants, out of which are elected two head burgesses, one for the city, and the other for the liberties. Another officer is the high constable, who has all the other constables under his direction. See London.

WESTMORELAND, one of the most northern English counties. It is separated from the sea-shore by a narrow strip of the county of Lancaster, which bounds it on the south and south-west, as do Cumberland on the north and north-west, and Yorkshire on the east. It is of very irregular shape. Its greatest length is forty, and its greatest breadth thirty-five miles. According to the best estimate, it contains 762 square miles, or 489,680 British statute acres. It is divided into four wards, distinguished by the prefixes of East, Kendal, Lonsdale, and West, which are again divided into thirty parishes.

The population of the several wards in 1831 was found to be, of the West Ward, 7884; of the East Ward, 14,455; of Kendal Ward and Kendal Town, 27,252; and of Lonsdale Ward, 5448.

The population of the whole county amounted in 1801 to 41,617, in 1811 to 45,922, in 1821 to 51,350, and in 1831 to 55,041. At the last-mentioned period the males were 27,576, and the females 27,465. The dwelling-houses were 10,353, inhabited by 10,984 families. Of the families, 4454 were chiefly employed in agriculture; 4116 were chiefly employed in trade, manufactures, and handicraft; and the remaining 2414 were comprised in neither of the preceding classes. By the census of the same year, the number of males twenty years of age was 14,020; the occupiers of land employing labourers, 1435; the occupiers of land not employing labourers, 1685; the labourers employed in agriculture, 3474; persons employed in manufactures or making manufacturing machinery were 1074; in retail trade or handicraft as masters or workmen, 3621; the capitalists, bankers, professional, and other educated men were 602; the labourers in labour not agricultural were 1195; the other males twenty years of age (except servants), 746; male servants twenty years of age 188, and under twenty years 66; and the female servants 2576. This county is the least densely peopled of any in England.

The greater part of the county consists of bleak and barren moors, and groups of lofty and naked mountains. The valleys between these mountains, through which the rivers wind, are of moderate fertility, and when well cultivated yield good crops of oats, and in some few instances of wheat and barley. The better parts of these valleys are appropriated to feed cattle or produce hay. The acreable value of the land, in the whole of this county, is much lower than that in any other part of England. According to the returns under the income-tax, the average annual rent and tithes together did not exceed 8s. 7d. per acre, being about half the average value of the rest of the kingdom. The romantic prospects, however, which are afforded by the contrast between the mountains and the lakes, more than repay the traveller for rambling at his leisure through the fine scenery. The lakes of Winandermere and Ulleswater are partly in this county, and those of Grasmere and Hause Water, with several smaller lakes, provincially called Tarns, wholly so. Besides the char (a fish almost peculiar to these lakes), trouts, pikes, perch, and eels, are taken abundantly in these waters.

The cattle of Westmoreland are of the long-horned kind, and attain a large size when well fed. The butter they afford is highly valued, and supplies to some extent the markets of the metropolis. Large flocks of sheep are fed on the mountains, which yield a coarse wool; but by crossing the breed the wool of late years has been much improved. Numbers of geese are fed on the moors, and these, with hams, form a part of the exports of the county. Westmoreland is nearly destitute of coals, and the metallic ores lie so deep, or are in so remote situations, that there is none of them worked. Slates of the finest quality are abundant, and large quantities of them are exported. Limestone is also very plentiful.

The principal manufactures of the county are chiefly carried on at Kendal, a place early celebrated for the woollen cloth which bore its name. This manufacture, and that of linsey-woolsey, as well as of coarse worsted stockings, are still continued; and considerable progress has recently been made in introducing the making of cotton goods. It appears by the parliamentary returns, that in 1831 the town of Kendal was in a state of such activity as to employ between 500 and 600 males, upwards of twenty years of age, in making cotton checks, kerseys, linseys, blanketing, and other goods. Woollen goods are made at Kirkland and some other places, and gunpowder at Sedgwick and Longdales, while the cotton trade of Kendal and its vicinity has been remarkably extended.

The principal rivers are the Eden, the Lune, the Ken or Kent, and the Lowther, which are more remarkable for the beauties displayed on their borders, and for the abundance of fish they contain, than for any facilities they afford to intercourse. None of them is navigable, nor are there any artificial canals.

The county gives the title of earl to the family of the Fanes, and that of Lonsdale to the Lowthers, and recently the title of Baron Brougham to the head of the family of that name, and of Langdale to the Master of the Rolls. Two members of the House of Commons are returned for the county. The town of Kendal with its townships, and those of Kirkland and Nether Graveship, have been created a borough by the reform law, and elect one member; and by the same law the ancient borough of Appleby has been disfranchised.

The most remarkable seats of noblemen and gentlemen are the following: Lowther Castle, earl of Lonsdale; Appleby Castle, earl of Thanet; Abbot Hall, Christopher Wilson, Esq.; Mint House, J. H. Long, Esq.; Netherdale Hall, John Mounsey, Esq.; Brougham Hall, Lord Brougham; Carlton Hall, Lord Wallace.

The town of Kendal contains 10,015 inhabitants, and Kirby Lonsdale 1686. No other town in the county has a population of 1500.[1]

WESTERN Port, on the south coast of New Holland, a capacious bay, with a considerable island at the entrance, which lies in lat. 38. 33. S.

WESTPORT, a seaport town in the county of Mayo, distant from Dublin, by way of Tuam, 134½ miles. The town is beautifully situated in a small valley, which is watered by a stream running through the centre of the two principal streets. There are various minor streets which diverge on both sides of the valley, and, from the acclivity of the ground, are very steep. Great inconvenience arises from the port and the town being separated by the seat of the marquis of Sligo, and by the steepness of the road between the two places. The town is increasing in prosperity, arising from the agricultural produce of the neighbouring district being shipped here, from the quantity of linen which is still made, and the business which a large distillery and brewery have called forth. The amount of custom-duty collected at the port in 1838 was L.5044; in 1839, L.9121; and in 1840, L.7555. In addition to the parish church, which is situated in the demesne of the marquis of Sligo, there are places of worship in the town for the Presbyterians and Methodists, and a large chapel for the Roman Catholics. The population in 1821 amounted to 4326, and in 1831 to 4448.

WESTRAY, one of the largest of the Orkney Islands, containing, in 1831, 2025 inhabitants. See Orkney.

WETLUGA, a circle of the Russian government of

---

Kostroma. It extends in north latitude from 57° 8′ to 58° 33 and in east longitude from 45° 6′ to 47° 48′. The soil is poor, and the climate raw and cold, better adapted for pasturage than for agriculture; and the population, much dispersed, does not exceed 30,000 persons. The capital is the city of the same name, 437 miles from St Petersburg. Long. 45. 35. E. Lat. 57. 40. N.

WETSTEIN, John James, a learned biblical critic, was born at Basel in 1693. On his admission to the ministry, he maintained a thesis "De variis Novi Testamenti Lectionibus;" in which he showed that the great variety of readings of the New Testament affords no argument against the authenticity of the text. He had made these various readings the object of his attention, and travelled into foreign countries to examine all the manuscripts he could find. In 1730, he published "Prolegomena ad Novi Testamenti Græci Editionem accuratissimam," &c. Some divines, dreading his unsettling the present text, procured a decree of the senate of Basel against his undertaking, and even got him prohibited from officiating in the ministry; on which he went to Amsterdam, where the Remonstrants named him to succeed the famous Le Clerc, then superannuated, as professor of philosophy and history. His edition of the New Testament he published in 1752, in 2 vols. folio. He left the text as he found it, placing the various readings, with a critical commentary, underneath; subjoining two epistles of Clemens Romanus, till then unknown to the learned, but discovered by him in a Syriac manuscript of the New Testament. He died at Amsterdam in 1754.

WETTER Isle, in the Eastern Seas, situated off the north coast of the island of Timor. It is about sixty-five miles in length and twenty in average breadth. Long. 126. 4 E. Lat. 7. 24. S.

WETTEREN, a large market-town of the Netherlands, in the province of East Flanders and circle of Dendermond. It stands on the river Scheldt, and contains 7750 inhabitants, chiefly employed in making linen and fine thread. There is a handsome bridge over the river.

WEXFORD, a maritime county in the province of Leinster, in Ireland, is bounded on the north by Wicklow, on the east by St George's Channel, on the south by the Atlantic, and on the west by Waterford, Kilkenny, and Carlow. It lies between 52° 4′ and 52° 48′ north latitude, and 6° 5′ and 7° 1′ west longitude; extending fifty-five miles in its greatest length from north to south, and thirty-four in its greatest breadth from west to east, and comprehending an area of 882 square miles, or 564,479 acres, of which 545,979 are cultivated, and 18,500 uncultivated mountain or bog. It ranks as the fourteenth county in superficial extent, and the ninth in that of cultivated land.

The county was first known as the settlement of the Brigantes and of the Menapii, whose chief town, Menapia, is supposed to have been either Ferns or Wexford; the latter holding the northern parts, with part of Wicklow, the former the southern and western, with a portion of Waterford. It was afterwards known by the name of lighion or South Leinster. It suffered severely by the predatory incursions of the Danes, who, after ravaging the open country, and burning Ferns, then the capital, made a permanent settlement, of which the town of Weisford or Wexford was the principal position. They retained possession of the district until the arrival of the English, who, in 1169, landed at Bagenbon, near Bannow, under the command of Robert Fitzstephen, Maurice Fitzgerald, and Hervey de Montmorency, and took the town of Wexford, which M'Murrough, king of Leinster, to whose aid these adventurers had come into the country, granted to Fitzstephen, together with the adjoining district of Forth, at the same time bestowing on Montmorency the neighbouring district of Bargie. The latter grant was confirmed by Henry II. on his arrival; but that conferred on Fitzstephen was taken from him and made part of the palatinate of Leinster, which the same king granted to Strongbow, the first undertaker of the adventure, and chief leader of the forces. The district descended, through the female line, to William earl Marshal, on whose demise, without male issue, it was portioned out among his five daughters, the second of whom, wife of Warren de Mountchency, obtained Wexford. In consequence of the frequent changes of seigniory, the district fell into a state of great distraction, and was partly seized on by the Kavenaghs, the descendants of M'Murrough, who assumed the title of kings of Leinster. It was reduced to shire-ground by King John in 1210, and the lordship having ultimately descended to the earl of Shrewsbury, the county was separated into two parts, the Liberty and the Cross; the former being governed by authorities appointed by the earl, the latter by officers of the crown. Each sent two members to the Irish parliament, until the property of the earl became vested in the crown, under the statute of absentees, passed in 1537. During the civil wars of 1641, it was held for the royal party, until reduced by Cromwell, whose operations were signalized by much cruelty. Since that event, the county remained in a tranquil state until the year 1798, when it became the principal seat of the insurrection in the southern counties; the town of Wexford forming the head-quarters of the insurgents, and several severe conflicts taking place at Enniscorthy, New-Ross, and other positions, with the royal forces.

The surface consists chiefly of a collection of very low hills, except on the northern and western sides, on the former of which it rises into an elevated ridge, forming the southern termination of the great Wicklow group. Its loftiest points are, Slieveboy, 1384 feet high; Kilkevan, 1063; Connar Hill, 1491; and Croghan-Kinshela, 1985. On the latter or western side it is bounded by the rugged chain of Mount Leinster, 2604 feet high, and Blackstairs, 2411, ranging from north to south. The county boundary on this side is continued southwards by the Barrow and the estuary of Waterford harbour. Within the county are the Camerous Hills and Carrickburne, respectively 598 and 766 feet; Lackan, near New-Ross, 628; Tarah Hill, a striking landmark on the eastern coast, 825; and Forth Mountain, 774 feet. The south-eastern extremity, containing the baronies of Forth and Bargie, forms a peninsula of low land, nearly shut out from the rest of the county by the last-mentioned range of mountains and by Wexford harbour. The principal river is the Slaney, which enters the county at its north-western extremity, from Wicklow, and traverses it in a south-eastern direction, till it falls into Wexford harbour at Carrigg, noted for the remains of an ancient Norman fortress, erected by Fitzstephen immediately after his landing. The whole course of this river is marked by a succession of picturesque scenery; and it receives in its progress a number of tributary streams, of which the Bann is the most remarkable. The Slaney is navigable for small barges to Enniscorthy. The Bannow, which discharges itself into a bay of the same name, claims notice solely from its historic reminiscences. The Barrow forms the western boundary, from the foot of Blackstairs Mountain, to its confluence with the Suir, in Waterford harbour. Lough Ta, near Carnsore Point, is the only lake in the county. It is supplied by the ingress of several small streams, and having no natural outlet, it increases rapidly in extent, covering the surrounding low land, until, in every second or third year, its accumulated waters are drawn off by an artificial cut, which discharges them into the sea. The coast on the eastern side, from Arklow southwards to Wexford, is very dangerous, having no place of refuge in case of foul weather, except in the small artificial harbour of Courtown, fit only for small craft. The dangers of navigation are increased by a succession of sand-banks from that of Arklow, Wexford.

the south point of which is marked by a floating light. These are called Kilgorman, the Rusk and Ram, and Blackwater Bank. Wexford harbour forms a large and safe landlocked basin; but the entrance to it is obstructed by a bar, on which at times there is not more than seven feet water; and in the passage up to the quay there are several shifting banks, that render the navigation hazardous even to those acquainted with it. Within the harbour are the two small islands of Beg-Eri and Great Island, on each of which are the remains of monastic buildings. The Tusker Rock, about five miles from shore, between Greensore and Carnsore Point, has on it a revolving light, with two faces bright and one deep red. Bells are also rung in foggy weather. South of the coast, and west of Carnsore Point, are the two Saltee islands. South of them is a floating light; and between them and the mainland is a narrow ridge, called St Patrick's Bridge, with but from seven to ten feet of water on it at ebb tide. Farther west are the fishing harbours of Crosfarnogue and Fethard. The latter is a creek, dry at low water. Still farther, the projecting point of Hookhead, forming the eastern side of Waterford harbour, and having on it a light-house 100 feet high, forms the western extremity of the coast, which thence tends northwards to the mouth of the Barrow, having on it Duncannon Fort, that commands the entrance to that river and to the port of Waterford.

The basis of nearly the whole county is a stratum of clay-slate, graywacke, and graywacke-slate, interrupted by several small patches of quartz rock near Gorey, one of larger size south of Wexford, and another south of Enniscorthy. A small protrusion of greenstone trap, with whin-dykes, appears to the north of Gorey. The carboniferous or mountain limestone shews itself to the south of Wexford, along the shore of the harbour. It forms also the extremity of Hookhead Point. Mount Leinster and Blackstairs are a continuation of the great granite formation of Wicklow, constituting its southern termination, which is here broken through by the valley of the Barrow or New-Ross river. On its eastern verge it is bordered by clay-slate, passing into greenstone-slate. Granite also shews itself in two patches south of Carnsore Point. The Saltees are of clay-slate, supporting beds of sandstone. Slates are raised in several places. A lead-mine at Cairn, after having been worked for some time, and abandoned, has been re-opened. Silver was formerly raised at Clonmines, where it is said that the Danes established a mint for its coinage. Copper ore has been discovered near Wexford, and remains of ancient mines are visible in several places. A perfect skeleton of the great moose-deer of Ireland, found in a bog, is now in a private collection in the county. The soil in the south-eastern parts is a rich alluvial mould, mixed with coralline sand and limestone. The peninsula of Hookhead, which rests on a limestone bed, is peculiarly fertile, both throwing up a rich herbage, and yielding heavy crops of grain. The quality of the soil deteriorates on proceeding westward; but the farmer finds a valuable equivalent in these districts, in the large tracts of turf or peat-moss with which its surface is overspread.

The progress of the population, according to the calculations most deserving of credit, has been as follows:

Year.	Authority.	Total Inhabitants.
1760	De Burgo	66,804
1792	Beaufort	115,000
1812	Parliamentary census	160,000
1821	Ditto	170,806
1831	Ditto	182,991

The latest of these returns shows a population of one inhabitant to every three acres of land of all kinds, or of 1 to every 2·95 of cultivated land. The return of the Commissioners of Public Instruction, made in 1834, but which, being collected in dioceses instead of counties, cannot be deemed strictly accurate, gives a total of 187,497 souls, of which 21,602 were members of the established church, 317 Protestant dissenters, and 165,578 Roman Catholics. The number of children receiving instruction in public schools, as stated in returns made to parliament at various periods, is as follows:

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821	7,924	3930	—	11,854
1824–6	10,951	7233	585	18,769
1836–7	2,174	1637	—	3,811
1837–8	2,280	1789	—	4,069
1838–9	2,825	1748	—	4,573

According to the return of 1824–6, in which alone notice is taken of the religious persuasion of the pupils, the numbers of each were as follows: Members of the established church, 2298; Protestant dissenters, 30; Roman Catholics, 15,641; those whose religious persuasion could not be ascertained, 100. The number of schools, as stated in the same return, was 380, of which 34, having 2278 pupils, were maintained by grants of public money; 24, with 1943 pupils, by voluntary subscriptions; the remaining 322, with 14,548 pupils, wholly by the fees paid for instruction. There is an endowed school at Ferns, on the foundation of Erasmus Smith, in which the master receives an annual salary of L.30, in addition to the pupils' fees. At New-Ross there is a school, founded by Sir John Ivory, with an additional endowment from the corporation.

The county is divided into the eight baronies of Ballaghkeen, Bantry, Bargie, Forth, Gorey, Scarewalsh, Shelburne, and Shelmalier. These are subdivided into 143 parishes, all, except two in the diocese of Dublin, being within that of Ferns, which is nearly conterminous with the county. The diocese was united with that of Leighlin until after the passing of the act for reducing the number of sees in Ireland; under the provisions of which the united dioceses were in 1835 joined to that of Ossory, and the three are now held by one bishop, who is a suffragan to the archbishop of Dublin. Previously to the union, the county was represented in the Irish parliament by eighteen members, two for the county, and two for each of the boroughs of Bannow, Clonmines, Enniscorthy, Fethard, Newborough, New-Ross, Taghmon, and Wexford. By the act of union the number was reduced to four; two for the county, and one each for New-Ross and Wexford, which arrangement has been continued under the reform act. The number of electors for the county, immediately previous to the passing of that act, and at several subsequent periods, was as follows:—

Year.	No.	Year.	No.	Year.	No.
1831	1686	1834	3006	1837	3567
1832	3007	1835	3006	1838	3567
1833	2907	1836	3567	1839	3567

The number of electors is to that of the total population as 1 to 51, and to that of the heads of families as 1 to $8\frac{1}{2}$. The county is in the Leinster circuit. The assizes are held in Wexford, and general sessions of the peace at the same place, and in Enniscorthy, Gorey, and New-Ross, twice in the year: in each of these last-named towns there are bridewells. The local government is vested in a lieutenant, sixteen deputy-lieutenants, seventy-four unsalaried magistrates, and a stipendiary. Under these there is a constabulary force, consisting of a county inspector, seven sub-inspectors, eight head constables, and 240 constables and sub-constables. The county infirmary, house of industry, and fever hospital, are in Wexford. There are also fever hospitals in seven other towns, and numerous dispensaries throughout the county. Wexford, Enniscorthy, Gorey, and New-Ross, have been fixed on as sites for the workhouses of poor-law unions.

The Forth mountain divides the county into two districts, di ring as widely from each other in character as if they we in separate islands. The country to the south of this m ntain, containing the baronies of Forth and Bargie, is pe led by the descendants of the English colony which wa located here in the time of Henry II. Their manners, cu oms, mode of dress, and even in a great degree their lar uage, still retain traces of the peculiarity of their origin. Th appearance of these baronies, when viewed by a spectat placed on the summit of their boundary ridge, is not un e the south of Devonshire. The entire district is well pe led. The farm-houses, as in Devonshire, are built of cla and thatched, with neat offices, and generally a vegetab e garden attached to them. The unwearied and well-di ted industry of the farmers insures a large return from th land. The whole is under tillage, and the vicinity of th sea enables the farmer to obtain a plentiful supply of se weed and calcareous sand for manure, besides which ma is found in abundance. Fuel is scarce; but the want of urf is supplied by the use of furze, which thrives here lu riantly, and with which the mounds of earth that form th general fence of the farm are thickly topped; thus insu ng at the same time the most perfect security against tr pass, shelter for the cattle in severe weather, and a suppl sufficient though not profuse, of fuel from the prunings of he furze. The fences are sometimes further fortified by hedge of quicksets along the centre of the top of the m nd. It is said that there was a turbary along the shore, w ch the encroachments of the sea have long ago covered w sand, and with water during flood-tides. The principa crops are barley and beans: these are to be seen, in the pe nsula of Carne, growing luxuriantly on land so oversp ad with stone as to induce the opinion that the ground w wholly unproductive. Poultry of every kind is reared in ll the farm-houses, chiefly for exportation to Dublin an Liverpool. Many farmers pay much attention to the re ing of bees, and efforts are frequently made to preserve th stock while taking the honey. The sandy reaches near th coast form burrows for immense numbers of rabbits, th flesh of which is deemed to be of a peculiarly good fl our. The shores are frequented by numerous flocks of w and sea fowl, among which the barnacle is most highly pr ed. Round fish is taken in large quantities on the easte extremity of Nymph Bank, which is off the coast; and al at the station of the floating light off the Saltees. The in ore fishing employs many hands, their open boats being en bled to run for shelter during rough weather into the n merous creeks and inlets which indent the coast. Shellfi is plenty. The Wexford oyster is carried to Dublin, w re it finds a ready market, more on account of size than fl our. Wexford town is the chief market for the produce o he farms; and many of the inhabitants have never trav ed farther, looking on all beyond the mountain as a f ign country. An elderly woman, the wife of a respectab farmer, in answer to a question as to the extent of her tr elling through the country, replied, "that she had n er been out of Forth. On one unlucky day, indeed, sh had been prevailed upon to go to the top of the mounta ; but the sight of the wide world that there opened o her overcame her: her head grew giddy, her stomach si ened, and she hastened home, determined never again to e ose herself to such a hazard." The dialect of the peasa ry, of which some vestiges are still preserved in comm n conversation, was Saxon-English of the time of the H ries and Edwards. The rector of a parish there, when re ling Chaucer's Canterbury Tales while overseeing his re ers in a field, was struck with the similarity between m y words in his book and the expressions he heard from th e around him. On reading some passages of it to them, he was peculiarly struck with the surprise and pleasure e ressed by them when they found themselves able to understand what was written in a book. They were fully competent to interpret what was read, and gave explanations of phrases and passages which to him were abstruse, in a manner more satisfactory than the commentators whose notes were annexed to the printed text. Their usual mode of saluting each other is simple and pleasing. On meeting, one asks, "Is it long since?" meaning to inquire whether the interval of absence has appeared long. The reply is couched in similar terms of artless courtesy—"Yea, joy." The young people are passionately addicted to festive amusements, such as dancing and hurling. At their marriages, which in other respects are celebrated according to the forms usual elsewhere, an apple is cut into small pieces and thrown among the crowd, a custom derived from England, but the origin of which is unknown. The dress of the peasantry until lately was, for the men a jacket or short coat, waistcoat, and trunk breeches, with a round narrow-brimmed hat; for the women a short jacket and petticoat, bordered at bottom with several rows of coloured ribbon or tape; the head-dress was a kerchief. The people live comfortably, are industrious, cleanly, and well-conducted. The poorest farmer eats meat twice in the week, and the table of the wealthier is covered with butcher-meat and fowl. The usual beverage is home-brewed ale or beer of excellent flavour and colour. The women do all manner of field-work, except ploughing, and receive equal wages with the men. The manners and customs of the inhabitants of the other baronies resemble those of the Irish peasantry throughout the surrounding counties: there is less attention to external appearance and to domestic comfort and cleanliness. The soil also is poorer, and the farming less precise. There is, however, no disinclination to exertion, no want of the application of personal labour: the defect lies in its misdirection. In the western baronies, where there is neither sea-weed, marl, nor limestone, the petty farmer will take long journeys to draw home a load of lime, forty load of which are required to manure an acre. Beans are everywhere a favourite, though an uncertain crop. Wheat is sown in quantities sufficient to render it an important article of export. In most respects the system of tillage or the description of crops differs little from those of similar soils elsewhere. But it is observed, that even in those districts of the northern baronies in which the soil is good, abounding with marl alternating with a clayey loam, and adequate, by proper management, to give an abundant return to well-directed industry, little is perceptible of the activity, comfort, or happiness of the southern baronies. This difference is most striking on the estates in which the practice of letting lands to middle-men is most prevalent.

The manufactures carried on in the county are those of woollen cloth, checks, and coarse linens, all for the home-consumption of the district, and wrought in the farm-houses. A cotton factory near Enniscorthy failed. Iron was also manufactured in the same neighbourhood. At present the raising of grain and rearing of cattle is almost exclusively the occupation of the inhabitants, and the export of the agricultural produce the sole article of commerce. The principal markets for grain and flour are Wexford, Enniscorthy, and New-Ross. Much butter is sent to Dublin through Gorey; and much also is exported to Liverpool, together with swine and poultry. The exports of the county through Wexford have been estimated at 30,000 tons, value L.330,000; and the imports through the same channel at 40,000 tons, value L.600,000. The communication with the counties in the interior is carried on chiefly by the Barrow, which is navigable for barges to Athy, where it meets the Grand Canal. A line of railroad from Wexford to Carlow has been surveyed by the Commissioners of Railways, but no steps have as yet been taken towards its formation. There are five banking establishments; one a branch of the Bank of Ireland, one of the Provincial

Wexford.

Bank, and two National Banks. Eight loan-societies have been formed under the loan-fund act, in all of which the amount of loans in the hands of borrowers at the close of 1839 was L.6728, and the number of borrowers during the year 7356.

Every part of the county, but more particularly the southern baronies, abound with reliques of Danish, Saxon, and Norman antiquities. Raths are very numerous. There are two of considerable magnitude near Dunbrody, and two others near Enniscorthy and New-Ross. A heap of stones, near Wicklow Gap, at the northern extremity of the county, marks the spot where the bodies of those who fell in a sanguinary conflict there, between the king's troops and the insurgents in 1798, were interred together. The pile is constantly on the increase, as, according to the custom of the country, every passenger, as he travels onwards, adds a stone to the heap, and offers up a prayer for the repose of the souls of the deceased. The abbey of Dunbrody, situate near the confluence of the Suir and Barrow or Ross river, still exhibits the remains of one of the finest monastic buildings in Ireland. Tintern Abbey, called also "De Voto," was built by William Marshal, near the Bannow, on the spot where he landed after a storm, in performance of a vow made by him while in peril. On the head of Bagenbon, at the mouth of the same river, are the vestiges of a strong earthen intrenchment called Strongbow's Camp; but it was more probably that of Fitzstephen and his followers on their first landing. Ferns Castle, built by Strongbow, continued to be looked upon as a place of great military importance to the time of Cromwell's campaigns, and as such was also occupied during the insurrection of 1798. Enniscorthy Castle, built by Raymond le Gros at the same period with the former, was also a place of strength in the time of Cromwell, and in 1798 was used as a prison by the insurgents while in possession of the town. Buttermilk Castle, or Cuislan-na-Blahie, consists of two small dark towers at the foot of a steep hill near Dunbrody; it was used as a toll-house for the adjoining pass across the river, and as a place to receive and cure the fish due to the monks. Duncannon Fort was erected during the alarm of the threatened invasion of the Spanish Armada in the reign of Elizabeth. It is still kept up as a military position, having a bomb-proof magazine, and arrangements for mounting forty-two guns, with suitable accommodations for a garrison.

Wexford, the county-town, is situate on the southern side of the mouth of the Slaney, where it falls into Wexford haven. It was founded by the Danes, and after having been taken by the English on their first landing in Ireland, became a place of some importance. It obtained a charter in 1318, which was confirmed and enlarged by James I. in 1608. A parliament was held in it by the earl of Desmond in 1463. At the breaking out of the war of 1641, it took part with the Irish, and continued in their possession till taken in 1649 by Cromwell, either by force or treachery, when the inhabitants, like those of Drogheda, were subjected to military execution. In the war of 1688 it declared for King William, and in the insurrection of 1798 was seized and occupied by the insurgents until their main body was utterly defeated at Vinegar Hill near Enniscorthy. The town still retains many vestiges of antiquity. The streets are narrow and winding. It is connected with the northern part of the county by a wooden bridge, 1570 feet long, thrown across the Slaney, on which a toll is payable for maintaining it, under the superintendence of a board of commissioners. A broad quay proceeds from the bridge along the border of the haven for upwards of half a mile, which, with the haven itself, is under the management of a board called the quay commissioners. The corporate jurisdiction of the town under the charter of James is vested in a mayor, burgesses, and commons. The mayor holds a court of record for pleas to any amount, and there is also a court of conscience for debts under 40s. The county court-house, prison, house of correction, infirmary, and fever-hospital are in the town. There is also a small lunatic asylum, subsidiary to the district asylum for the county, which is at Carlow. The borough exercised a prescriptive right of returning two members to the Irish parliament, which number was reduced to one at the union, and still continues so. The number of electors in 1839 was 350. By the municipal corporation act for Ireland the corporation has been dissolved, and power is granted to form a new corporate body, according to conditions expressed in the act, under the name of "the mayor, bailifs, free burgesses, and commonalty of the town or borough of Wexford." By the same act the corporations of Gorey and New-Ross have also been dissolved, and provision made for their reconstruction, as in the case of Wexford; the former to be styled "the sovereign, bailifs, and free commonalty of the borough and town of Newborough;" the latter "the sovereign and burgesses of New-Ross." Eight fairs are held during the year. The town is the principal place of export for the county. Together with the suburbs, it forms an ecclesiastical union, consisting of eleven parishes, in which there are two churches. There are also several Roman Catholic chapels, some of which belong to monastic institutions. The population was, in 1821, 8326; in 1831, 10,673; and in 1834, 14,670. Of the last-named number, the members of the established church were 2031, the Protestant dissenters 28, and the Roman Catholics 12,641; the Protestants being to the Roman Catholics as 1 to 6. The population of the other towns in the county whose numbers exceed 1000 each was, in 1831, Enniscorthy, 5955; New-Ross, 5011; Gorey, 3044; Newtown Barry, 1430; and Taghmon, 1109. (C. P.)

WEYRE, a town of Hindustan, province of Agra, belonging to the rajah of Bhurtpore. It is well fortified, and is situated on the high road from Agra to Jeypore. Long. 77. 2. E. Lat. 27. 2. N.

WHAMPOA, a seaport of China, situated on an island in the river Canton, about two miles below Canton city. Here is a safe anchorage for large ships, which carry on their communication with Canton by boats. The island on which Whampoa is situated is called Bankshall island, from being the place where storehouses are constructed of bamboos and mats, to contain the ships' stores, &c. Immediately on the arrival of any vessel, two custom-house boats are placed alongside, to prevent smuggling; and without their permission no goods can be shipped or landed. All European ships are allowed to wear a flag in their boats, which prevents their being stopt at the custom-house. Lat. 23.6.N.

WHARTON, Philip, Duke of, a nobleman of the most brilliant parts, but of the most whimsical, extravagant, and inconsistent turn of mind, was the son of Philip marquis of Wharton. He was educated at home; and his father's great aim was to render him a complete orator. At a very early age he married a young lady, the daughter of Major-general Holmes, which disappointed his father's views of disposing of him in such a marriage as would have been a considerable addition to the fortune and grandeur of his illustrious family; yet that amiable lady deserved infinitely more felicity than she met with by this alliance. This precipitate marriage is thought to have hastened the death of his father; after which the son, being free from paternal restraints, and possessing a fortune of L.16,000 a year, plunged into those excesses which rendered him, as Pope expresses it,

> A tyrant to the wife his heart approv'd,
> A rebel to the very king he lov'd.

In the beginning of the year 1716 he began his travels; and as he was designed to be educated in the strictest Whig principles, Geneva was thought a proper place for his esidence. He first passed through Holland, and visited everal courts of Germany; and being arrived at Geneva, co eived such a disgust against his governor, that he left hi and set out post for Lyon, where he wrote a letter to th Chevalier de St George, who then resided at Avignon, an presented him with a very fine stout horse; which the ch alier no sooner received than he sent a man of quality to m, who took him privately to his court, where he was en rtained with the greatest marks of esteem, and had the tit of duke of Northumberland conferred upon him. He ho ever remained there but one day, and then returned to L n, whence he set out for Paris. He likewise paid a vi to the dowager of James II. then residing at St Germ ns. During his stay at Paris, his winning address and ab ties gained him the esteem and admiration of all the B ish subjects of rank of both parties.

bout the latter end of December 1716, he arrived in E land, whence he soon after set out for Ireland, where, th gh still under age, he was allowed the honour to take hi seat in the House of Peers, as earl of Rathfarnham and m quis of Catherlough. Notwithstanding his former condu t, he immediately distinguished himself as a violent partisa for the ministry; and in consequence of his zeal the king cr ted him a duke. He no sooner came of age than he w introduced to the House of Lords in England with the sa e blaze of reputation. In a little time he opposed the c rt, and appeared one of the most vigorous in defence o he bishop of Rochester; and soon afterwards he printed h lucubrations twice a week, in a paper called " The T e Briton," several thousand copies of which were circ ted.

The duke's boundless profusion had by this time so burd ed his estate, that by a decree of Chancery it was veste in the hands of trustees for the payment of his debts, a wing him a provision of L.1200 per annum for his subs ence. This being insufficient to support his title with s table dignity, he went abroad, and appeared to great adv tage at the imperial court. From thence he made a t r to Spain. The English minister was alarmed at his a ival, fearing that his grace was received in the charact of an ambassador. The duke received a summons u ler the privy seal to return home; but instead of obeyi it, he endeavoured to inflame the Spanish court against t t of Great Britain, for exercising an act of power, as he c ls it, within the jurisdiction of his Catholic majesty. He t n acted openly in the service of the Pretender, and was r eived at his court with the greatest marks of favour.

While his grace was thus employed, his neglected duchess d in England on the 14th of April 1726, without issue. l soon afterwards fell violently in love with Miss Obyrne, e of the maids of honour to the queen of Spain, the ghter of an Irish colonel, whose fortune chiefly con ted in her personal accomplishments. All his friends, particularly the queen of Spain, opposed the match; t he falling into a lingering fever, occasioned by his dis pointment, the queen gave her consent, and they were n after married. He then spent some time at Rome, ere he accepted of a blue garter, assumed the title of ke of Northumberland, and for a while enjoyed the con ence of the exiled prince. But not always keeping thin the bounds of Italian gravity, it became necessary him to remove from hence; when, going by sea to rcelona, he wrote a letter to the king of Spain, acquaint him that he would assist at the siege of Gibraltar as a lunteer. Soon after he wrote to the Chevalier de St eorge, expressing a desire to visit his court; but the che lier advised him to draw near to England.

The duke seemed resolved to follow his advice; and set g out with his duchess, arrived in Paris in May 1728, ence he soon after proceeded to Rouen, where he took his residence; and was so far from making any concession to the government of England, that he did not give himself the least trouble about his estate, or any other concern there, though, on his arrival at Rouen, he had only about L.600 in his possession, and a bill of indictment was preferred against him in England for high treason. Soon after, the chevalier sent him L.2000, which he squandered away in a course of extravagance, when, to save the charges of travelling by land, he went from Orleans to Nantz by water, and staid there till he got a remittance from Paris, which was squandered almost as soon as received. At Nantz he was joined by his ragged servants, and from hence took shipping with them for Bilboa, when the queen of Spain took the duchess to attend her person. About the beginning of the year 1731, the duke, who commanded a regiment, was at Lerida, but declined so fast that he could not move without assistance, yet when free from pain did not lose his gaiety. He however received benefit from some mineral waters in Catalonia; but soon after relapsed at a small village, where he was utterly destitute of all the necessaries of life, till some charitable fathers of a Bernardine convent removed him to their house, and gave him all the relief in their power. Under their hospitable roof he languished a week, and died on the 31st of May, without one friend or acquaintance to close his eyes; and his funeral was performed in the same manner in which the fathers inter the members of their own fraternity. He died without issue, and his titles became extinct. The duchess survived till February 1777.

Two octavo volumes, published under the title of his Life and Writings, include seventy-four papers of the True Briton, and his speech in defence of Atterbury. Other two duodecimo volumes likewise bear his name; and the same life occurs in a publication called " The Poetical Works of Philip late Duke of Wharton, and others of the Wharton Family, and of the duke's intimate acquaintance," &c. Lond. 1731, 2 vols. 8vo. On such a collection as this no reliance can be placed. Ritson intended to publish an edition of the duke's genuine poems, accompanied with an account of his life.

WHEAT. See AGRICULTURE.

WHEEL, in *Mechanics*, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on its axis. See MECHANICS.

WHEEL is also the name of a kind of punishment to which great criminals are put in divers countries. In some, assassins, parricides, and robbers on the highway, are said to be condemned to the wheel, when they are to have their bones first broken with an iron bar on a scaffold, and then to be exposed, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself. Of this cruel punishment it is not certain who was the inventor: it was first used in Germany, and was indeed but rarely practised anywhere else, till the time of Francis I. of France, who, by an edict of the year 1534, appointed it to be inflicted on robbers on the highway.

WHEEL-Carriages. See MECHANICS for an account of the general principles.

WHEELER, SIR GEORGE, a learned traveller and divine, was the son of Colonel Wheeler of Charing in Kent, and was born in 1650 at Breda, where his parents, as royalists, were then in exile. In 1667 he became a commoner of Lincoln College, Oxford, but did not take a degree. He travelled through various parts of Greece and the East, in company with Dr Spon of Lyon; and taking orders on his return, was installed a prebendary of Durham, made vicar of Basingstoke, and afterwards rector of Houghton le Spring. He published an account of his Journey into Greece in 1682 in folio; and in 1689 an Account of the Churches and Places of Assembly of the primitive Christians, from the Churches of Tyre, Jerusalem, and Constantinople, described by Eusebius. He is likewise author of a work entitled "The Protestant Monastery, or Christian Oeconomics." In 1702 he was created D. D. by diploma. He died in 1724.

WHIDAH, a kingdom of Africa, on the coast of Guinea, and to the west of the Gold Coast; extending about ten miles along the sea. It is a populous country, well furnished with large villages; and there are so many small ones, that they are not above a musket-shot from each other. Whidah was conquered by the king of Dahomy. Its trade consists of slaves, elephants' teeth, wax, and honey.

WHIDBEY'S ISLES, seven small islands on the south coast of New Holland, about seven or eight miles from Whidbey Point, which is a rocky promontory in long. 135. 6. W. and lat. 34. 36. S.

WHIRLPOOL, an eddy, vortex, or gulf, where the water is continually turning round. Those in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous.

WHIRLWIND, a wind which moves in a spiral direction, as well as horizontally, which is exceedingly rapid and impetuous, but only of short duration. Of some kinds of whirlwinds the motion is slow, and they are only injurious by their vortex; while others seem to do mischief as well by their progressive as their whirling motion. Of this kind are those called *typhons*, which, by their frequently following the course of rivers, seem thus also to discover their electrical origin.

WHISKEY, a term signifying *water*, and applied in Scotland and in Ireland to a distilled liquor drawn from barley.

WHIST, a well-known game at cards, which requires great attention and silence; hence the name.

WHISTON, WILLIAM, an English divine of a singular character, was born the 9th of December 1667, at Norton, near Twycrosse, in the county of Leicester, where his father was rector. He was admitted of Clare Hall, Cambridge. In 1693 he took the degree of A.M., and became a fellow. He afterwards began to take pupils; but his ill health at length forced him to decline this occupation. Having entered into orders, he became chaplain to Dr More, bishop of Norwich, in 1694; and in this station he published his first work, entitled "A New Theory of the Earth," in which he undertook to prove the Mosaic doctrine of the earth perfectly agreeable to reason and philosophy. This work brought no small reputation to the author. In the beginning of the eighteenth century he was made Sir Isaac Newton's deputy, and afterwards his successor, in the Lucasian professorship of mathematics; when he resigned a living he had in Suffolk, and went to reside at Cambridge. About this time he published several scientific works, explanatory of the Newtonian philosophy; and he had the honour to be one of the first, if not the very first, who rendered these principles popular and intelligible to the generality of readers. About the year 1710, he was known to have adopted Arian principles, and was forming projects to support and propagate them. He had translated into English the Apostolic Constitutions, which favoured the Arian doctrine, and which he asserted to be genuine. The consequence was, that in 1710 he was deprived of his professorship, and expelled from the university. He nevertheless pursued his scheme, by publishing the next year his Primitive Christianity revived, 4 vols. 8vo, for which he incurred the censure of the convocation. On his expulsion from Cambridge, Mr Whiston settled in London, where, without suffering his zeal to be intimidated, he continued to write and propagate his primitive Christianity, with as much ardour as if he had been in the most flourishing circumstances. In 1721 a subscription was commenced for the support of his family, and it amounted to L.470. Though he drew profits from reading astronomical and philosophical lectures, and also from his publications, which were very numerous, yet these of themselves would have been very insufficient; nor, when augmented by the benevolence and charity of those who loved and esteemed him for his learning, integrity, and piety, did they prevent his being frequently in great distress. He long continued a member of the church of England, and regularly frequented its service, though he disapproved of many things in it; but at last he went over to the Baptists, and attended Dr Foster's meeting at Pinner's Hall, Broad Street. Among other performances not specified above, he wrote Memoirs of his own Life and Writings, which contain some curious particulars.

He was remarkable for speaking the plainest truths on every occasion, and to persons of every degree. During the year 1725, when Whiston, with Dr Clarke, Dr Berkeley, and others, had the honour to attend Queen Caroline on a certain day of every week, to discuss the progress of science, her majesty one evening took occasion to pay him a just compliment on his truth and integrity, requesting that he would, with his usual plainness, point out to her any fault that he might have observed in her conduct. At first he begged to be excused, adding, that few persons could bear to have their faults plainly told to them, and least of all royal personages, who, from their elevation, are necessarily surrounded by flatterers, to whose lips truth is a stranger. Her majesty replied, that he was to consider her not as a queen, but as a philosopher; and that philosophy is of very little use, if it cannot enable its professors to bear without offence truths necessary to their own improvement. Upon this he told her, that the greatest fault which he had observed in her conduct, was her indecent behaviour in the house of God, which, he assured her, had made very unfavourable impressions on the minds of many persons, who, coming to town from distant parts of the country, had gone to the chapel to obtain a sight of her majesty, the king, and the royal family. The queen made no reply; but in about six weeks afterwards renewed her request, that Mr Whiston would point out the most glaring improprieties in her conduct. To this he answered, that he had laid down a maxim, from which he could not deviate, never to point out to any person more than one fault at a time, and never to give a second reproof till he had observed some good consequence to have arisen from the first.[1] Much to the queen's honour, she was pleased with this plain dealing, and continued to think favourably of Mr Whiston. This honest, but whimsical and credulous man, died on the 22d of August 1752, in the eighty-fifth year of his age.

WHITAKER, JOHN, was born at Manchester on the 27th of April 1735. His father, James Whitaker, does not appear to have been in affluent circumstances. At the age of ten, the son was sent to the free-school, and in 1752 was removed to Oxford upon an exhibition of ten pounds a year. He was entered of Brasen-nose College, but on the 2d of March 1753 was elected scholar of Corpus Christi. He proceeded A. M. in 1759, and in the following year was ordained deacon and priest. On the 21st of January 1763 he was elected fellow of his college, and on the 1st of July 1767 took the degree of B. D. At Oxford, we are informed, "his uncommon vigour of intellect at once displayed itself among his acquaintance; but whilst his animated conversation drew many around him, a few were repelled from the circle by his impatience of contradiction (a

---

[1] Bishop Berkeley was present at these conversations, and from his son we received the account which we have given of them. They are likewise mentioned, but not so accurately, by Bishop Newton in his own Life.

Whitaker.

fing which almost ever accompanies powers like his), and b the consciousness, it should seem, of their own inferio- ri." That his conversation must have displayed sufficient v acity, and his temper sufficient warmth, may very easily b conceived; but through these lines of panegyric, it is ipossible not to discern a strong ray of truth; namely, th from the earliest period of his literary career, he was d inguished by a bold and dogmatical spirit, which could il endure dissent or opposition. This may indeed be con- si ered as his first and last characteristic; and although the z l of a friend has, with some degree of dexterity, endea- v red to convert it into a topic of praise, by representing it s the ordinary mark of a superior mind, we are not very n ch inclined to regard it in the same light. The doctrine s ms indeed to be of a somewhat dangerous tendency; t e calculated for misleading young candidates for lite- r y honours, who may thus be induced to supply, by arro- g ce and dogmatism, what is wanting in sound learning a l solid judgment. It may be asserted, without much h ard of confutation, that this overweening and dogmatical s it is at least as frequently the characteristic of those w o possess but a very moderate stock of real merit; who h e perhaps made no uncommon progress in any branch o science or literature, and yet consider themselves as en- t ed to decide all controversies, and to adjust all claims to i ellectual distinction.

For many years he served the curacy of Bray in Berk- s re for Dr Berkeley, a son of the famous bishop of Cloyne; a l was subsequently curate of Newton in Lancashire. I gave the first conspicuous proof of his abilities by the p blication of "The History of Manchester." Lond. 1771, 4. The second volume followed in the year 1775; but a hough four books were originally promised, only two are t is completed; they embrace the Roman, British, and xon periods of the history. This work, which is perhaps t most remarkable of his publications, was immediately r garded as the production of no ordinary writer, but as re conspicuous for bold and ingenious speculation, than f cool and judicious discussion. Like the other works of t same author, it is written in a lively and rambling man- r. His impatience and vivacity rendered him incapable selecting his topics, and condensing his thoughts; and adhering to his usual method of writing, a large book y he produced on almost any subject. Before he had ought this work to a close, he published "The genuine story of the Britons asserted." Lond. 1772, 8vo. This lume is chiefly directed against the historical work of Mr cpherson, better known as the foster-father of Ossian; d both publications have been considered by compe- t judges as adding very little to the real stock of infor- tion.

In the course of the following year we find him residing the metropolis, and officiating as the morning preacher Berkeley chapel. For this appointment he was indebted a Mr Hughes; but their connexion was of a very short ration, for he was removed from his situation in less than o months. He thought proper to communicate his ievances to the public, in "The State of the Case be- een Mr Whitaker and Mr Hughes, relative to the Morn- g Preachership of Berkeley Chapel." Lond. 1774, 4to. is resentment was so strong, and his discretion so weak, t he thus subjected himself to the vexation of a lawsuit, and the Court of King's Bench held his printed Case to be a libel.

On the 23d of August 1777, he succeeded to the rectory Ruan-Lanyhorne, one of the most valuable livings in the gift of his college. He now withdrew into Cornwall, and took possession of his benefice; and he afterwards married Jane Tregenna, a lady of an ancient Cornish family. Her great-grandfather, grandfather, and father, were successively rectors of Mawgan in Pydar. For a long time his retirement was not attended with peace and studious ease. His restless and domineering disposition soon involved him in a long train of contentions with his parishioners: he proposed a tithe-composition, which his friends represent as by no means unreasonable, but of which his parishioners appear to have entertained a different opinion; they refused to accede to his proposal, and he demanded the tithes in kind. "Disputes," we are informed, "arose upon disputes; animosities were kindled; and litigations took place. That Mr Whitaker was finally victorious, afforded pleasure to the friends of the rector, *and to the friends of justice and truth;* yet it was long before harmony was restored to Ruan-Lanyhorne." Let us here remark in passing, that this mode of confounding the cause of religion with the cause of tithes is a pretty ancient device. It is not certainly to be considered as wonderful, if, after all these contentions and litigations, Mr Whitaker was subjected to the mortification of observing that his parishioners manifested an aversion to his preaching, an indifference to his admonitions, and a repugnance to his authority. This is indeed the natural consequence of the measures to which he resorted; they have an obvious tendency to excite or continue animosities, and to circumscribe the utility of a clergyman, by rendering him obnoxious to almost every man in his parish who has property enough to bring him within the circle of such litigations. It may perhaps be regarded as extremely doubtful whether any clergyman, possessing a portion of the primitive spirit of Christianity, would be tempted to engage, more especially with his own flock, in quarrels, disputes, and lawsuits, which there might be any decent means of avoiding. We are informed, that after the lapse of a few years, Mr Whitaker had the satisfaction of perceiving a visible alteration in the behaviour of his principal parishioners, and that a good understanding was at length established between the pastor and his flock. His manner was hearty and familiar; and notwithstanding the rabid spirit that sometimes animates his writings, he was possessed of many virtues, though meekness and humility were certainly not of their number.[1]

His next publication was of a professional kind, namely, "Sermons upon Death, Judgment, Heaven, and Hell." Lond. 1783, 12mo. He afterwards engaged in the famous controversy respecting the character of Queen Mary, and produced an immense work under the title of "Mary Queen of Scots vindicated." Lond. 1787, 3 vols. 8vo. He published an enlarged edition in the year 1790; and he seems to have been not a little mortified that neither Lord Hailes nor Dr Robertson could be induced to print a single page against him. This production, which is by no means eminent for coolness of reasoning, or sobriety of manner, has probably convinced very few competent judges of historical evidence, who have submitted to the labour of a patient investigation. If Mary's innocence is so apparent as some of her advocates aver, is it not remarkable that so many bulky volumes should be required to display that innocence? Besides, if we suppose her to be innocent, we must, at the same time, suppose all the most distinguished of those who opposed her after the murder of her husband, to be covered with an enormous load of infamy. And we will only venture to add, that the uncontroverted history of her proceedings, from a short period preceding the murder, till her indecent nuptials with Bothwell, furnishes a degree of moral evidence which seems to be ineffectually opposed by all the persevering sophistry of her defenders.

---

[1] In reference to this paragraph, the coadjutor of Mr Baines is pleased to remark, that "Mr Whitaker's memory has been unjustly as- led, and his integrity wantonly called in question, by an anonymous writer in the Supplement to the Encyclopædia Britannica." (History the County Palatine and Duchy of Lancaster, vol. ii. p. 386. Lond. 1836, 4 vols. 4to.) The most careless reader may perceive that t one word is uttered against his integrity; nor has this writer undertaken to prove that it afforded any indication of his piety or wisdom, maintain against his own parishioners a series of litigations for the space of twelve years. "In this contest Mr Whitaker's law expenses ounted to about a thousand pounds; but, by taking the tithes in kind during the suits, he not only made up this loss beyond the original oduce of the tithes, but was several hundred pounds in pocket....But the *conscientious minister* looked with a deeper concern to the iritual welfare of his flock. He saw, with sorrow, their aversion from his preaching, their indifference to his instruction, their repugnance his authority;" and certainly no result could be more natural. An injudicious defence is sometimes more injurious than a wanton attack.

Having again recurred to his theological studies, Mr Whitaker published a large volume, entitled "The Origin of Arianism disclosed." Lond. 1791, 8vo. Whatever might be the opinion of others,[1] it is clear that the author himself entertained a favourable enough opinion of this production; which he represents as "a train of historical argumentation, at once novel in its direction, comprehensive in its scope, and decisive in its efficacy." If he could not discuss a point of history without heat and violence, it is easy to conceive how he would be disposed to discuss a point of heresy. As a proof of his zeal for orthodoxy, an anonymous friend presents us with the following anecdote. "That the feeble Deist should have shrunk from his indignant eye, may well be conceived, when we see his Christian principle and his manly spirit uniting in the rejection of a living of considerable value, which was at this time offered him by an Unitarian patron. He spurned at the temptation, and pitied the seducer." But in order to render this anecdote altogether intelligible, some further information seems to be required. Were his principles so pure and rigid that he could only accept of preferment from a patron of confirmed and approved orthodoxy? Or did this nameless patron offer him the living under the condition, express or implied, that he should become a convert to the Unitarian creed? With respect to the first question, it is quite evident that many pious divines have accepted of preferment from patrons who, to all human appearance, had no religion whatsoever; and with respect to the second, it is equally evident, that no patron, if he possessed common sense, could expect a beneficed clergyman to make an open avowal of opinions which the church has formally condemned as heretical.

Whitaker had contributed to the English Review a series of articles on Gibbon's history, which were now reprinted in a separate form, under the title of "Gibbon's History of the Decline and Fall of the Roman Empire, in vols. iv. v. and vi. quarto, reviewed." Lond. 1791, 8vo. This work, which extends to a considerable volume, is written in his usual vein, with sufficient acuteness and animation, but with little suavity of manner or elegance of style. He certainly detects errors and exposes inconsistencies; but it may readily be supposed that a writer of his cast of mind was not very likely to form an impartial estimate of Gibbon's real merits, which, after all the fair and necessary deductions are made, must still be allowed to be very great. Whitaker is always an intrepid writer; he is never afraid to deliver a decided opinion; and whether the subject is very familiar or quite new to him, his tone of decision is commonly the same. Thus, for example, in his animadversions on Gibbon's admirable chapter relating to the Roman jurisprudence, he is pleased to declare, that "nothing can subdue the native barrenness of such a field as this." His censure refers to a subject of which he may be considered as in a state of almost total ignorance: he seems to have been alike unacquainted with this science, and incapable of appreciating the masterly manner in which it is here discussed. It may indeed be affirmed that there is no portion of Gibbon's work more remarkable than this very chapter: although his early studies had not prepared him for such a task, he has yet exhibited a rapid and powerful sketch of the Roman jurisprudence, to which it might be difficult to find a parallel in the writings of the professed civilians. And it has accordingly been stamped with the approbation of some of the most distinguished civilians of the present age. It has been illustrated by Hugo and Warnkönig, the former having published it in German, and the latter in French.

After an interval of three years, Whitaker produced a copious work on a subject which is certainly curious and interesting. This work he entitles, in his usual form, "The Course of Hannibal over the Alps ascertained." Lond. 1794, 2 vols. 8vo. Like some of his former publications, it attracted a considerable degree of attention, and, like them, was found to contain many hasty and erroneous opinions. On this ground he was encountered by the late Lord Woodhouselee, who published, but without his name, "A Critical Examination of Mr Whitaker's Course of Hannibal over the Alps ascertained." Lond. 1795, 8vo. In the year 1795, he endeavoured to enlighten the public by an octavo tract on "The real Origin of Government," which we have never had the pleasure of seeing, but which his friend, formerly quoted, describes as a very singular pamphlet. This information may, without scruple, be received as authentic; for it is not difficult to conjecture how the subject of civil government would be treated by such a writer at such a period.

The last work which Whitaker lived to communicate to the public is "The Ancient Cathedral of Cornwall historically surveyed." Lond. 1804, 2 vols. 4to. His vigour was still undiminished, and he had formed the plan of many other works, particularly a history of Oxford, and a history of London: the former he intended to comprise in an octavo volume, the latter he contemplated as "quite new and original, and fit to make a quarto." While he was prosecuting his ardent researches into the antiquities of the metropolis, his friends remarked the first indications of declining health. He had originally possessed a robust constitution, but his mind was restless, and his temper ardent; and during his last visit to London, his great exertions in procuring materials for his work, and his great efforts in supporting his usual tone of conversation in the literary circles, left him in a state of debility which was not at first considered as alarming. It was however followed by a stroke of palsy, from which his recovery was never so complete as to allow him to resume his occupations with his former vigour. During the last year of his life, he lingered in a state of gradual decay; and he is said to have contemplated his approaching dissolution with the cheerful resignation of a Christian. On Sunday the 30th of October 1808, he sank as into a quiet slumber, without any indication of suffering, and with a smile on his countenance. He died at Ruan-Lanyhorne, in the seventy-fourth year of his age. Of his three daughters, two survived him. One of these, named Anne, was married in 1821 to Dr Taunton, a physician of Truro. Whitaker's widow, who is described as the last of her ancient family, died at Truro in 1828, at the age of eighty-five.

He had recently sent to the press an antiquarian volume, which, after his death, was published under the title of "The Life of Saint Neot, the oldest of all the Brothers of King Alfred." Lond. 1809, 8vo. He had likewise made some progress in preparing a life of Queen Mary; and his materials were consigned by his widow to Mr George Chalmers, who adopted them as the foundation of his own extraordinary performance. All his principal works have now been enumerated, but a few supplementary notices are still necessary. He wrote an introduction to Flindell's Bible, and a supplement to Polwhele's Antiquities of Cornwall, and was a contributor to "The Cornwall and Devon Poem." His connection with the English Review has already been mentioned; but he likewise appears to have lent his aid to the British Critic and the Antijacobin Review; and his eulogist informs us, in a very solemn style, that "the strength of his principles is nowhere more apparent than in those articles where he comes forward, armed with the panoply of truth, in defence of our civil and ecclesiastical constitution. It was there he struck his adversaries with consternation, and we beheld the host of Jacobins shrinking away from before his face, and creeping into the caverns of darkness." The same tasteful and judicious writer avers, that at Whitaker's lucubrations "a Gibbon trembled;" but this panegyric is somewhat abated by another piece of information, namely, that Gibbon was a "feeble Deist." With what torrents of fiery indignation this worthy divine must, in his fugitive and anonymous writings, have overwhelmed Jacobins and heretics, may very easily be imagined by those who have inspected his more elaborate works, bearing his name and addition, and intended for the benefit of posterity. Some persons of cooler tempers, and of more habitual candour, when they are fairly enveloped in the cover of a review, may now and then be tempted to speak in a very high and arrogant tone to men greatly elevated above their own standard, and of subjects of which they only possess a very casual and superficial knowledge.

---

[1] "I confess this book has satisfied me how little erudition will gain a man now-a-days the reputation of vast learning, if it be only accompanied with dash and insolence. It seems to me impossible that Whitaker could have written well on the subject of Mary Queen of Scots, his powers of judgment being apparently so abject." (Coleridge's Literary Remains, vol. iv. p. 306.)

This anonymous writer, whom we strongly suspect to be Mr Polwhele, has, in the following passage, discussed the character of Whitaker with more sobriety and discrimination. "It is true, to the same warmth of temper, together with a sense of good intentions, we must attribute an irritability at times destructive of social comfort, an impetuousness that brooked not opposition, and bore down all before it. This precipitation was in part also to be traced to his ignorance of the world; to his simplicity in believing others like himself—precisely what they seemed to be; and, on the detection of his error, his anger at dissimulation or hypocrisy. But his general good humour, his hospitality, and his convivial pleasantry, were surely enough to atone for those sudden bursts of passion, those flashes which betrayed his 'human frailty,' but still argued genius. And they who knew how 'fearfully and wonderfully he was made,' could bear from a Whitaker what they could not so well have tolerated in another. In his family, Mr Whitaker was uniformly regular; nor did he suffer at any time his literary cares to trench on his domestic duties. The loss of such a man must be deemed, as it were, a chasm both in public and private life. But, for the latter, we may truly say, that if ever wife had cause to lament the kind and faithful husband, or children the affectionate parent, or servants the indulgent master, the family at Ruan-Lanyhorne must feel the loss irreparable."[1] (x.)

WHITBURN, a parish and village situated on the high road from Edinburgh to Glasgow, in the county of Linlithgow. The inhabitants of the village are mostly weavers. It contains two places of worship belonging to the dissenters. In 1831 the population of the parish amounted to 800.

WHITBY, a seaport town in the north riding of the county of York, in a locality distinguished as the Liberties of Whitby Strand, 242 miles from London. It stands at the mouth of the river Eske, which divides it into two parts; and it consists of several streets, which are steep and narrow. The mouth of the river forms the harbour, which is protected from the fury of the ocean by two outer and inner piers. Adjoining the inner harbour are spacious dock-yards and dry docks. The trade of the town is extensive, many ships being employed in the coal and freestone trade; and near it are some extensive alum-works, which add to its commerce. The business of ship-building is carried on, and, with the subsidiary branches connected with it, creates occupation for a large class of the inhabitants. Whitby is a place of great antiquity, as there are records of a convent having been built there by Oswy, king of Northumberland, in the seventh century; which was afterwards destroyed by the Danes, and was restored to its former splendour after the Norman conquest. The town has, by the act of 1832, received the right of returning one member to the House of Commons. It has no corporate body. There are places of worship for the various bodies of dissenters, and also a number of benevolent institutions for the relief of the destitute. The market is on Saturday, and is well supplied with all provisions. The population amounted in 1821 to 8697, and 1831 to 7765.

Whitby, *Daniel*, a learned divine, was born at Rushden in Northamptonshire in the year 1638. In 1653 he was admitted of Trinity College, Oxford, and was elected a scholar in 1655. He took the degree of A. B. in 1657, and of A. M. in 1660. In 1664 he was elected a fellow of his college, and about the same time began to distinguish himself by the publication of some controversial works against the papists. The credit which he thus obtained recommended him to Dr Ward, bishop of Salisbury, who appointed him his chaplain, and in 1668 collated him to two different prebends in that cathedral. In 1672 he was admitted precentor of the same church, and about the same time took the degree of D. D. He was likewise preferred to the rectory of St Edmund's at Salisbury; but his next publication had no tendency to advance him in the church. It appeared anonymously, under the title of "The Protestant Reconciler; humbly pleading for Condescension to Dissenting Brethren in things indifferent and unnecessary, for the sake of peace, and shewing how unreasonable it is to make such things necessary Conditions of Communion." Lond. 1683, 8vo. The churchmen of that period were unprepared for the reception of such doctrines; and the author was immediately exposed to a storm of controversial abuse. The bishop obliged him to make a formal retractation; and in a second part of the Protestant Reconciler, he endeavoured in some measure to recover the good opinion of his more bigoted brethren. He now sent to the press a treatise on a less hazardous subject; "Ethices Compendium, in usum academicæ juventutis." Oxon. 1684, 8vo. His most important work, the principal labour of fifteen years, was his Paraphrase and Commentary on the New Testament, published in 1700, in two volumes folio. He afterwards published additional annotations, and an "Examen variantium Lectionum Johannis Millii in Novum Testamentum." Among the other works which he produced, we must not overlook "The Necessity and Usefulness of the Christian Revelation, by reason of the Corruptions of the Principles of Natural Religion among Jews and Heathens." Lond. 1705, 8vo. In 1710 he published two works against Calvinism. One of these, a Discourse with a long title, is commonly described as Whitby on the five Points. In 1711 he published a Latin treatise on original sin. According to Bishop Tomline, he confuted Calvinism almost to a demonstration; but the bishop was himself a very slender and superficial theologian. One of Dr Whitby's

Whitefield.

works might be advantageously reprinted in the present state of controversial discussion: "Dissertatio de Scripturarum Interpretatione secundum Patrum Commentarios." Lond. 1714, 8vo. The scope of this dissertation is to evince, by copious examples, that the fathers are for the most part very incompetent and unsafe guides in matters of theological controversy. Dr Whitby had now become a decided Arian; and to these opinions, apparently derived from Dr Clarke, he adhered till the time of his death. Having preached at St Edmund's church on the preceding day, he died on the 24th of March 1726, at the age of eighty-eight. Of the changes in his creed he left an account in "The last Thoughts of Dr Whitby, containing his Correction of several Passages in his Commentary on the New Testament. To which are added five Discourses." Lond. 1727, 8vo. This posthumous publication was accompanied with an account of his life by Dr Sykes.

WHITCHURCH, a market-town of the county of Hants, in the hundred of Evingar, and division of Kingsclere, fifty-seven miles from London. It is an ancient borough, and returns one member to parliament. It is now a place of little trade, with a small market on Friday. The river that runs by it produces the finest trout, and is much visited by anglers. The population amounted in 1821 to 1434, and in 1831 to 1673.

WHITCHURCH, a market-town of the county of Salop, in the hundred of North Bradford, 160 miles from London. It is a well-built place, whose greatest ornament is the parish church, erected in 1722. It is a fine building of the Tuscan order, standing on the site of an ancient Gothic structure, having a stately square tower with eight bells, and elaborately finished in the interior. There is also an excellent endowed grammar-school, with houses for the several masters. There is a well-attended market on Friday. The population, which is principally employed in the malt and hop trade, and in making shoes, amounted in 1821 to 5376, and in 1831 to 5736.

WHITE, one of the colours of natural bodies.

WHITE FRIARS, a name common to several orders of monks, from being clothed in a white habit.

WHITE SEA is a bay of the Frozen Ocean, so called in the north part of Muscovy, lying between Russian Lapland and Samoieda; at the bottom of which stands the city of Archangel. This was the chief port possessed by the Russians before their conquest of Livonia.

WHITE ISLAND, in the South Pacific Ocean, near the east coast of New Zealand, north of Cape Runaway. Long. 186. 36. W. Lat. 26. N.

WHITEFIELD, GEORGE, was born at the Bell Inn, in the city of Gloucester, on the 16th of December 1714. He received his education at the grammar-school of that city, where he made some progress in classical learning; and his talents for elocution enabled him to appear to advantage in the speeches which he delivered before the corporation on their annual visitation. He was taken from school before he was fifteen, and, as his mother's circumstances were by this time much on the decline, he began to assist her in the business of the tavern. At the age of eighteen he was entered as a servitor at Pembroke College, Oxford, where he formed an acquaintance with Charles and John Wesley, and several other young men under religious impressions, who "lived by rule and method," and were therefore called Methodists. Whitefield soon adopted their opinions and manners; and so far did his enthusiastic disposition carry their ascetic practices, that his health became seriously injured. After a severe illness, which brought him to the brink of the grave, he found it necessary to retire to Gloucester for the benefit of his native air. His general character there, his demeanour at church, his visiting the poor, and praying with the prisoners, attracted the notice of Dr Benson, bishop of Gloucester, who informed him, that although he had resolved to ordain none under three and twenty (and Whitefield was only twenty-one), he should think it his duty to ordain him whenever he applied for holy orders. This offer Whitefield accepted, and was made deacon in 1736. The week following he returned to Oxford, took his degree, and diligently employed himself in the instruction of the poor and the prisoners. During the two succeeding years, by his preaching in London, Bath, Bristol, and other places, the fame of his eloquence was widely diffused, and immense multitudes everywhere attended upon him. In the year 1736 he went to officiate as minister at Dummeer in Hampshire; but being invited to join the Wesleys and other friends, who had gone out as missionaries to a new colony in Georgia, he went to London to wait on the trustees for Georgia. During his residence in the metropolis, he preached with remarkable success to crowded assemblies; and so great was the fame of his eloquence, that on Sunday mornings, long before day, the streets were filled with people going to hear him, with lanterns in their hands. In the latter end of December 1737 he left London and embarked for Georgia, which he reached in May 1738. After a residence of three months there, he found it necessary to return to England, in order that he might receive priest's orders, and that he might raise contributions for founding and supporting an orphan-house in the colony.

The separation of the Methodists, and their organization as a distinct sect, was daily becoming more inevitable; for after his return the clergy received him with great coldness, and excluded him from most of the parochial pulpits. He was therefore compelled to adopt some new method to preserve his usefulness. He accordingly went and preached in the open air to the colliers in the vicinity of Bristol; a numerous and lawless race, who had been totally neglected by the parochial clergy, and were as ignorant and savage as heathens. The second and third time of his preaching out of doors, his audience greatly increased, till it amounted to 20,000 persons. "The first discovery of their being affected," says Whitefield, "was by seeing the white gutters made by their tears, which plentifully fell down their black cheeks."

In August 1739 he embarked a second time for America, where he remained nearly two years. During his absence, however, his popularity had sensibly declined at home. The Moravians had made inroads upon the society, and John Wesley had not only preached, but printed, a sermon in favour of sinless perfection and universal redemption, and had exerted himself still more earnestly against the Calvinistic doctrines, to which Whitefield was strongly attached. The latter earnestly desired to avoid all disputes, and exhorted Wesley to brotherly kindness and forbearance; but the conduct of injudicious partisans on both sides soon rendered a separation inevitable. Shortly after his separation from Wesley, Whitefield's friends built a large shed for him near the Foundery (Wesley's Church). As it was merely a temporary structure, to screen the audience from cold and rain, he called it the Tabernacle. A fresh excitement immediately began, immense congregations were formed, and new scenes of usefulness opened upon him daily. Having been earnestly invited to visit Scotland by Ebenezer and Ralph Erskine, the founders of the Secession Church, he accepted the invitation in the year 1741, and commenced his labours in the Secession meeting-house in Dunfermline. Whitefield however was too liberal in his principles to limit the benefit of his services to any sect. "In every building," he said, "there were outside and inside workmen, and the latter was his province." And having differed from his new associates on this ground, he made a tour through the country, and with the greatest success preached in all the large towns to immense crowds. A large sum of money was contributed for the support of his orphan-school, and he was preserved with the freedom of the towns of Edinburgh, Glasgow, Aberdeen, Stirling, Paisley, and Irvine.

From Scotland he went at the end of October into Wales, where he married Mrs James, a widow. His marriage, like Wesley's, was not a happy one, and the death of his wife is said by one of his friends to have "set his mind much at liberty." Whitefield was irritable, and impatient of contradiction; and even if his temper had been more happily constituted, his habits of life rendered him unfit for the duties of a husband and a father.

On his return to London, his enthusiasm led him to engage in a singular contest with the showmen and others which then exhibited in Moorfields during the Whitsun holidays when, he said, Satan's children kept up their annual rendezvous. "This," says Mr Southey, "was a sort of pitched battle with Satan, and Whitefield displayed some generalship upon the occasion." Attended by a large congregation of "praying people," he began at six o'clock in the morning. Thousands who were waiting there for the usual sports all flocked around him. "Glad was I to find," says he, "that I had for once as it were got the start of the devil. Being thus encouraged, I ventured out again at noon, when the fields seemed all white, ready, not for the Redeemer's, but Beelzebub's harvest." Thinking that, like St Paul, he should now, in a metaphorical sense, be called to fight with wild beasts, he took for his text, "Great is Diana of the Ephesians." "I could scarce help smiling," says he, "to see thousands, when one of the choicest servants of Satan was trumpeting to them, upon observing me in my black robes and my pulpit, all to a man deserting him and flocking to hear the gospel. But this, together with a complaint that they had taken many pounds less that day than usual, so enraged the owners of the booths, that when I came to preach a third time in the evening, in the midst of the sermon a Merry-Andrew got upon a man's shoulders, and advancing near the pulpit, attempted to slash me with a long heavy whip several times. Soon afterwards they got a recruiting sergeant with his drums and fifes to pass through the congregation; but I desired the people to make way for the king's officer, which was quietly done." When the uproar became, as it sometimes did, so great as to overpower his single voice, he called the voices of all his people to his aid and began singing; and thus, what with singing, praying, and preaching, he continued upon the ground till the darkness made it time to break up. So great was the impression produced in this extraordinary scene, that he received 1000 notes from persons under conviction, and soon after about 350 persons were received into the society in one day.

In August 1744 he embarked a third time for America, where he continued his usual course of itinerant preaching for upwards of three years. On returning to England, after an absence of nearly four years, with a constitution shattered by his incessant labours and the unfavourable climate, he found his congregation at the Tabernacle nearly dispersed; and such was the depression of his own circumstances, that he was obliged to sell his household furniture to pay his orphan-house debts. But he now obtained an important accession to his cause, and a zealous propagator of his sentiments, from a quarter whence it was least expected, in the person of the countess of Huntingdon. That noble lady, who was, in will at least, as munificent a patron to the followers of Whitefield as the Countess Matilda was to the papacy, invited him to her house at Chelsea as soon as he landed; and after he had twice officiated there, she wrote to him inviting him again, that some of the nobility might hear him. A large circle attended, among whom were Lords Chesterfield and Bolingbroke. The former complimented the preacher with his usual courtliness; the latter is said to have been much moved at the discourse. The countess appointed Whitefield one of her chaplains; and gave most efficient support to the Calvinistic Methodists, by building and endowing chapels in various parts of the country, and by erecting a college for training up young men for the ministry. The remaining years of Whitefield's life were spent in the same incessant labours. He made several voyages to America; he visited Scotland thrice; he made a laborious excursion through the west and north of England, preaching, as usual, to immense multitudes; he visited Ireland twice, and on the second expedition narrowly escaped with his life from the fury of a Roman Catholic mob. It is stated by one who knew him well, that, "in the compass of a single week, and that for years, he spoke in general forty hours, and in very many sixty, and that to thousands." These unremitting labours at length exhausted his vigour. On his return from America to England for the last time, Wesley was struck with the change in his appearance. "He seemed," says he in his Journal, "to be an old man, being fairly worn out in his Master's service, though he had hardly seen fifty years." In 1769 he returned to America for the seventh and last time. His career was now drawing rapidly to a close. An asthmatic complaint had for some time been making inroads upon his constitution. When it first seized him, one of his friends expressed a wish that he would not preach so often, and his reply was, "I had rather *wear* out than *rust* out." His death was at last somewhat sudden and unexpected. He arrived at Newbury in New England on the evening of 29th September 1770, with the intention of preaching there the next morning. On retiring to rest, however, he was much disturbed, and complained heavily of an oppression on his lungs. The symptom was fatal, for he expired on the following morning, in the fifty-sixth year of his age. According to his own desire, he was buried before the pulpit, in the presbyterian church of the town where he died.

Whitefield.

The character of this zealous and enthusiastic divine, like most others possessing warm friends and bitter enemies, has been represented in very different lights. That he had much enthusiasm and some fanaticism in his disposition, is obvious both from his journals and letters. Like Wesley, he magnified the most trifling incidents into miraculous interpositions in his favour, and lent a ready faith to whatever marvels had a tendency to designate him as the favourite of God, or the peculiar object of Satan's fury. But in spite of these defects, it cannot be denied that his unwearied diligence in doing good, his zeal for the truth, his piety, his self-denial, his benevolence and boundless charity, justly entitle him to a place among the most distinguished men of his age. Whitefield had neither the inclination nor the abilities to render himself, like Wesley, the head and absolute ruler of a party; but he was as superior to his distinguished coadjutor in openness and simplicity of character, and in the absence of vanity and personal ambition, as he was inferior to him in intellect and learning. Franklin has justly observed, that it would have been fortunate for his reputation if he had left no written works, for his writings of every kind are below mediocrity; they afford the measure of his knowledge and of his intellect, but not of his genius as a preacher. Whitefield's great talent, in fact, was popular oratory; and though occasionally alloyed with some improprieties, both of language and manner, yet there was in all his discourses a force and vehemence and passion, a fervent and melting charity, and an earnestness of persuasion, which produced the most extraordinary effect upon all ranks and descriptions of people. Hume pronounced him the most ingenious preacher he had ever heard, and said it was worth while to go twenty miles to hear him. But perhaps the greatest proof of his persuasive powers was when he drew from Benjamin Franklin's pocket the money which that clear, cool reasoner had determined not to give: it was for the orphan-house at Savannah. "I did not," says the American philosopher, "disapprove of the design; but as Georgia was then destitute of materials and workmen, and it was proposed to send them from Philadelphia at a great expense, I thought it would have been better to have built the house at Philadelphia, and brought the children to it. This I advised, but he was resolute in his first project, rejected my counsel, and I therefore refused to contribute. I happened soon after to attend one of his sermons, in the course of which I perceived he intended to finish with a collection, and I silently resolved he should get nothing from me. I had in my pocket a handful of copper-money, three or four silver dollars, and five pistoles of gold. As he proceeded I began to soften, and concluded to give the copper; another stroke of his oratory made me ashamed of that, and determined me to give the silver; and he finished so admirably that I emptied my pocket wholly into the collector's dish, gold and all." (B. Q.)

WHITEHAVEN, a large seaport and market town in the parish of St Bees and ward of Allerdale, on the west coast of the county of Cumberland. It is situated at the upper end of a small creek of the Irish Sea, and comprises a number of handsome straight wide streets, which intersect each other at right angles, and are well paved, and lighted with gas. The town has advanced to its present state of prosperity from being, in 1566, a small place, containing six fishermen's huts. For this progress it is indebted to the family of Killigrew, and more particularly to their successors the Lowthers, who, having large estates around the town, and valuable possessions of coal underneath it, have liberally come forward, when opportunities occurred, to promote its prosperity. There are three churches, and various places of worship belonging to dissenters. The institutions for educational purposes are numerous, and educate more than 1700 children. There are also an infirmary, a fever hospital, a dispensary, and a house of industry. The public buildings, including a theatre and news-room, are well adapted for the instruction and amusement of the inhabitants, as well as for the business of the port. Its harbour is spacious and commodious, having seven piers extending into the sea in different directions, and affording ample security to the shipping. There is attached to the harbour a patent slip, erected at the expense of Lord Lonsdale. There are two light-houses at the entrance of the harbour, and a third is situated on the promontory of St Bees' Head, three miles to the south-west. The commerce of this port is very extensive; the principal export articles being coal, iron and lead ore, grain, and lime. The chief manufactures are coarse linens, and articles connected with the fitting out of vessels. The town contains iron and brass founderies, and breweries. The coal-works are, next to those of Newcastle and Sunderland, the most important in the kingdom, and are the principal source of wealth to the town. There are five principal shafts or entrances to the mines, called Bearmouths, three on the north and two on the south side of the town. They are 320 yards in depth, and extend to a considerable distance under the sea; and such vast quantities have been excavated that the mines have the appearance of a subterranean city. In 1837 the quantity of coals shipped from this port amounted to 405,593 tons, and in 1838 to 389,188 tons, exclusive of the cinders and culm. The net amount of customs-duties, after deducting all expenses, paid into the treasury, was, in 1837, L.95,895, and in 1838, L.97,300. There are upwards of 450 vessels belonging this port, engaged in the American, West Indian, Baltic, and coasting trade. Steam-vessels sail regularly to Liverpool, Carlisle, Dublin, the Isle of Man, Annan, Dumfries, Wigton, and Kirkcudbright. The town and port are governed by trustees appointed by the trading community and Lord Lonsdale. Whitehaven returns a member to parliament. The population in 1821 amounted to 12,438, and in 1831 to 11,393..

WHITHAM, a market-town and parish of the county of Essex, which gives its name to the hundred in which it is situated. It stands on a branch of the river Blackwater, thirty-eight miles from London and seven from Chelmsford. It is a well-built town, and pleasantly situated; and being on the great road to Harwich and Ipswich, has much travelling through it. Whitham is said to have been originally built by King Alfred. It afterwards belonged to the Knights Templars, who had a preceptory at Cressing, three miles distant. The church is a neat Gothic structure, containing some ancient monuments. There is a good market on Tuesday. The population amounted in 1821 to 2578, and in 1831 to 2735.

WHITHORN, a royal borough of Wigtonshire, situated eleven miles south of Wigton, and two and a half miles west of Wigton Bay. It consists chiefly of one street lying north and south, and nearly half a mile in length. The houses are not inelegant, though somewhat irregularly built. The only public buildings are the town-house and jail, the parish church, and three dissenting chapels. The town is devoid of manufactures, but maintains two branch banks. The population in 1831 amounted to 1305. The Isle of Whithorn, a village containing 413 inhabitants, about three miles to the south-east, is the port of the borough. The municipal government is vested in a provost, two bailies, and fifteen councillors; and Whithorn unites with Stranraer, Wigton, and New Galloway in sending a representative to the House of Commons. Registered voters in 1840-1, 50. Municipal revenue about L.100.

Whithorn is celebrated for its antiquity, and is conspicuous in the annals of the church. Its original name was *Candida Casa*, White Cottage, from the circumstance that, in the beginning of the fifth century, a church was erected there, of white stone, supposed to be the first in Scotland built of such solid materials. The founder of it was St Ninian, a native of the place, who died and was buried there in 432. His memory was held in such veneration that many places both in England and Scotland were called after his name, and pilgrimages were made to his shrine for centuries previously to the Reformation, when such superstitious practices were prohibited by act of parliament. The kings of Scotland not only visited this spot themselves, but encouraged others to do so, and granted protection to all strangers coming from England, Ireland, and the Isle of Man on pilgrimage to Whithorn. James IV. performed the pilgrimage several times; once *on foot*, in consequence of the dangerous illness of his queen on the birth of their eldest son; and on her recovery, which was attributed to the miraculous influence of the saint, her husband and she, in testimony of their gratitude, performed the same journey in circumstances of great pomp and magnificence. James V. was the last royal personage that paid a visit to St Ninian's shrine. Candida Casa continued till 1689 the seat of the bishop of Galloway, who, previously to the erection of Edinburgh into a bishopric in 1633, ranked above all the other Scotish bishops, and immediately after the archbishops of St Andrews and Glasgow. About the middle of the twelfth century, a monastery was founded at Whithorn by Fergus, Lord of Galloway, for monks of the Premonstratensian order. The most eminent persons connected with this monastery were James Beaton, afterwards archbishop of St Andrews and lord chancellor of Scotland, and Gavin Dunbar, afterwards successively tutor to James V., archbishop of Glasgow, and chancellor of the kingdom. Of the cathedral and monastic buildings scarcely any remains can be traced, except a few arches, particularly a very beautiful one of the Saxon order, and several vaults. (C. I.)

WHITSTABLE, a town of the county of Kent, in the hundred of the same name, and in the lathe of St Augustine, sixty miles from London. It is the chief port from whence the trade of Canterbury is conducted, being seven miles from that city. The chief articles conveyed by it to London are corn and hops, and the produce of an oyster-fishery near to it. It has a large parish church. The population amounted in 1801 to 1205, in 1811 to 1249, in 1821 to 1611, and 1831 to 1926.

WHITSUN FARTHINGS, otherwise called *Smoke-farthings*, or *Quadrantes Pentecostales*, a composition for offerings which were anciently made in Whitsun-week, by every man in England who occupied a house with a chimney to the cathedral church of the diocese in which he lived.

WHITSUN ISLAND, in the South Pacific Ocean, discovered by Captain Wallis in 1767, about four miles long and three wide. Long. 137. 56. W. Lat. 19. 26. S.

WHITSUNDAY, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them. It is called *Whitsunday*, or *White Sunday*, because this being one of the stated times for baptism in the ancient church, those who were baptized put on white garments, as types of that spiritual purity which they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called *Pentecost*, this festival retained the name of *Pentecost* among the Christians.

WHITSUNDAY CAPE, on the south side of the island of Kodiak, in the North Pacific Ocean. Long. 208. 4. E. Lat. 58. 14. N.

WHITSUNDAY ISLAND, or *Pentecost*, one of the New Hebrides, in the South Pacific Ocean, about thirty miles long by eight broad. Long. 168. 20. E. Lat. 15. 44. S.

WHITSUNDAY'S PASSAGE, a strait so called by Captain Cook, from the day on which he sailed through it in 1770, between Cumberland Island and the coast of New Holland.

WHITSUNTIDE BAY, the passage which separates the islands of Kodiak and St Hermogenes, which lie about sixty miles from the entrance of Cook's Inlet, in the North Pacific Ocean. It was so called by Cook, who was not aware that the land was here divided into two islands, and what he supposed to be a bay was the strait by which they were separated.

WHITTLESEY, a town of the county of Cambridge, in the isle of Ely. It stands on the great Bedford Level, seventy-six miles from London and twenty-six from Cambridge. It contains two parishes, St Andrew's and St Mary's, each with a church. It stands on a rich but insalubrious district; and near to it is the Mere, or lake of its name, formed by a branch of the river Nen, and numerous drains from the fens in Huntingdonshire. It is between five and six miles in length, and from two to three in breadth, and abounds in excellent fish. The population amounted in 1821 to 5276, and in 1831 to 6019.

WHYE, a town of Hindustan, province of Bejapoor, situated near the source of the river Krishna, and one of the places of Hindu pilgrimage. It now belongs to the British. Long. 74. 5. E. Lat. 18. 0. N.

WHYMEA BAY, on the north coast of the island of Woahoo. It was here that Mr Hergest, commander, Mr Gooch, astronomer, and a seaman of the Dædalus, going on with stores for Captain Vancouver, was seized by some of the inhabitants and killed in 1792. Long. 202. 51. E. Lat. 21. 38. N.

WHYMEA ROAD, on the south west-coast of the island of Attowai.

WHYTATAKEE, an island in the South Pacific Ocean, discovered by Captain Bligh of the Bounty. Long. 159. 41. W. Lat. 18. 52. S.

WHYTT, ROBERT, an eminent physician, born at Edinburgh on the 6th September 1714, was the son of Robert Whytt, Esq. of Bennochy, advocate. This gentleman died six months before the birth of this son, who had also the misfortune to be deprived of his mother before he had attained the seventh year of his age. After receiving the first rudiments of school-education, he was sent to the university of St Andrews; and after the usual course of instruction there, in classical, philosophical, and mathematical learning, he came to Edinburgh, where he entered upon the study of medicine under those eminent medical teachers Monro, Rutherford, St Clair, Plummer, Altson, and Innes. After learning what was to be acquired at this university, in the prosecution of his studies he visited foreign countries; and after attending the most eminent teachers at London, Paris, and Leyden, he took the degree of doctor of physic at Reims in 1736, being then in the twenty-second year of his age. Upon his return to his native country, he had the same degree conferred upon him by the university of St Andrews, where he had before taken, with applause, the degree of master of arts.

Not long afterwards, in the year 1737, he was admitted a licentiate by the Royal College of Physicians of Edinburgh; and the year following he was raised to the rank of a fellow. From the time of his admission as a licentiate, he entered upon the practice of physic at Edinburgh; and the reputation which he acquired for medical learning, pointed him out as a fit successor in the first vacant chair in the university. Accordingly, when Dr St Clair resigned his academical appointments, Dr Whytt was elected his successor on the 20th of June 1746, and began his first course of the institutions of medicine at the commencement of the next winter session. In 1752, he was elected a fellow of the Royal Society of London; in 1761, he was appointed first physician to the king in Scotland; and in 1764, he was chosen president of the Royal College of Physicians at Edinburgh.

But the fame which Dr Whytt acquired as a practitioner and teacher of medicine, was not a little increased by the information which he communicated to the medical world in different publications. His celebrity as an author was still more extensive than his reputation as a professor. His first publication, "An Essay on the Vital and other Involuntary Motions of Animals," although it had been begun soon after he had finished his course of medical education, did not come from the press till 1751, an interval of fifteen years from the time when he had finished his academical course, and taken his doctor's degree; but the delay of this publication was fully compensated by the matter which it contained, and the improved form under which it appeared. The next subject which employed the pen of Dr Whytt was one of a nature more immediately practical. His "Essay on the Virtues of Lime-Water and Soap in the Cure of the Stone" first made its appearance in a separate volume in 1752. His third work, entitled "Physiological Essays," was first published in the year 1755. This treatise consisted of two parts: 1st, "An Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals;" and 2dly, "Observations on the Sensibility and Irritability of the Parts of Men and other Animals, occasioned by Dr Haller's treatise on that subject." The former of these may be considered as an extension and farther illustration of the sentiments which he had already delivered in his Essay on the Vital Motions, while the latter was on a subject of a controversial nature. In both he displayed that acuteness of intellect and strength of judgment which appeared in his former writings.

From the time when his Physiological Essays were published, several years were probably employed by the author in preparing for the press a larger and perhaps a more important work than any yet mentioned, his "Observations on the Nature, Causes, and Cure of those Disorders which are commonly called *nervous*, *hypochondriac*, and *hysteric.*" The elaborate and useful work was published in the year 1764. The last of Dr Whytt's writings is entitled "Observations on the Dropsy in the Brain." This treatise did not appear till two years after his death, when all his other works were collected and published in one quarto volume, under the direction of his son and of his intimate friend the late Sir John Pringle. Besides these five works, he wrote many papers, which appeared in different publications; particularly in the Philosophical Transactions, the Medical Essays, the Medical Observations, and the Physical and Literary Essays.

At an early period of life, soon after he had settled as a medical practitioner in Edinburgh, he entered into the married state. His first wife was Miss Robertson, sister to General Robertson, governor of New York. By her he had two children, both of whom died in early infancy, and their mother did not long survive them. A few years after the death of his first wife, he married Miss Balfour, sister to James Balfour, Esq. of Pilrig. By her he had fourteen children, six of whom only survived him, three sons and three daughters. But his course of happiness was terminated by the death of his wife, which happened in the year 1764; and it is not improbable that this event had some share in hastening his own death, for in the beginning of the year 1765 his health was so far impaired that he became incapable of his former exertions. A tedious complication of chronical ailments at length terminated his life, on the 15th of April 1766, in the fifty-second year of his age.

WIASMA, a circle of the Russian government of Smolensko, extending in north latitude from 54° 55′ to 55° 30′, and in east longitude from 33° 15′ to 34° 25′. It is a poor district, in which are the sources of the river Dnieper. The capital is the city of the same name, on the river Wiasma. Like most old Russian cities, it is surrounded with weak walls. It was burnt by the French in 1812, but has been rebuilt, and is now stated to contain 2000 houses, mostly of wood, with 12,000 inhabitants, who carry on an extensive trade by the river with St Petersburg, chiefly in corn. It is 489 miles from St Petersburg. Long. 33. 5. E. Lat. 55. 6. N.

WIBURG, a circle of the Russian province of Finland, extending in north latitude from 60° 10′ to 61° 1′, and in east longitude from 28° 1′ to 30° 17′, and containing 3740 square miles, with 31,840 inhabitants. It is bounded on the north-west by Wilmanstrand, on the north by Kekholm, on the north-east by Ladoga, on the east by St Petersburg, on the south by the Bay of Finland, and on the west by Fredrisham. It is an undulatory district, with many morasses, extensive woods, and sandy wastes, which with much labour scarcely yield sufficient food for its scanty population. The principal river is the Sestra, which is the boundary towards St Petersburg. The chief town, of the same name, ninety-eight miles from St Petersburg, is in a bay in the Gulf of Finland. It contains 800 houses, with 3640 inhabitants. It has a small harbour, from whence is exported pitch, tar, tallow, flax, hemp, iron, and some deals, and where salt, coffee, and wine, are imported. Long. 28. 40. E. Lat. 60. 42. N.

WICK, a royal borough, situate on the bay of the same name, in the county of Caithness. It is distant from Inverness by Beauly and Tain 137½ miles. Wick is a town of considerable antiquity, and was erected into a royal borough in 1589. It stands in a low situation, and its streets are irregularly built and crowded together. Fever of a typhoid type is seldom absent, arising from the filthy state of the streets, shores, and houses, the putrescent effluvia which steam from the fish offals, and the over-crowded state of the houses, more particularly during the fishing season. The river Wick, which passes through the town, and divides it from Pulteneytown, tends in some degree to keep it clean. Contiguous to Wick are Louisburgh and Pulteneytown, which are both included in the parliamentary borough. The latter was commenced under the auspices of the British Fishery Society; and being built on higher ground, and well planned, is a regular and handsome addition to the original town. It is indeed three times larger, and in it are all the dwelling-houses of the better class of inhabitants. The public buildings are in good order, and well adapted for the purposes for which they were erected. The revenue of the borough is about L.75 a year, and its expenses are nearly the same. It is governed by a provost, two bailies, a treasurer, a dean of guild, and seven councillors. With Cromarty, Dingwall, Dornoch, Tain, and Kirkwall, it returns a member to parliament. The trade of Wick consists in the herrings, which are here cured and exported. The live-stock and grain trade are also carried on to a considerable extent; and, from the number of people assembled here from various quarters during the fishing season, an increased trade is then maintained for supplying their wants. The average number of boats employed in this fishery for the last ten years is about 900, and the average annual quantity of fish taken for the last twenty years is 88,500 barrels; but within a recent period the number of both has decreased. In 1829 the number of boats employed was 955; persons employed in all the branches, 11,780. In 1840 the number of boats employed was 765; persons 7882; barrels cured, 63,495, of which were exported 55,711. For a further account of the fisheries, see the article under that head in this work. In 1810 a harbour was completed for L.14,000; but, from the increase of the trade and herring fishery, it was found inadequate, and another having been commenced, was completed in 1831, at an expense of L.40,000; but unfortunately it is exposed to the swell of the sea. Besides the parish church, there are places of worship for the Seceders, Independents, Roman Catholics, and other five dissenting bodies. There are several rope-works, a distillery, a brewery, an iron-foundery, a gas-work, a ship-building yard, and various boat-building yards, in Wick and Pulteneytown. In the year 1840 the number of vessels belonging to the port was twenty-one, with a registered tonnage of 1154. The custom-duty collected in 1837 amounted to L.696, and in 1838 to L.1034. In 1831 the stationary population of the parish amounted to 9850; but during the fishing season it is increased by an influx of about 10,000 strangers.

WICKET, a small door in the gate of a fortified place, &c. or a hole in a door through which to view what passes without.

WICKLIFFE, John. See Wycliffe.

WICKLOW, a maritime county in the province of Leinster, in Ireland, is bounded on the north by Dublin county, on the east by St George's Channel, on the south by Wexford, and on the west by Carlow, a detached portion of Dublin, and Kildare. It lies between 52° 40′ and 53° 14′ north latitude, and 5° 57′ and 6° 46′ west longitude, extending forty miles in its greatest length from north to south, and thirty-three in its greatest breadth from east to west, and comprehending an area of 781 square miles, or 500,178 acres, of which 405,039 are cultivated land, 94,100 uncultivated mountain or bog, and 1039 covered with water. It ranks as the eighteenth county in superficial extent, and the seventeenth in that of cultivated land.

According to Ptolemy the geographer, the northern part of the county was the residence of the tribe of the Cauci, and the southern that of the Menapii. It was afterwards occupied by the Irish septs of the Byrnes and O'Tooles, who, though the district was claimed by the English after their settlement, as part of the county of Dublin, maintained their independence, and carried on an almost continual war against the new settlers, until the end of the reign of Elizabeth, after whose death the district was made shire-ground by her successor James I. in 1605, and placed under the jurisdiction of English magistrates. The inhabit ts adhered to the royal cause during the war of 1641, unt the arrival of Cromwell, to whose superior force they su itted without opposition. No other occurrences of his rical importance took place until the year 1798, when sev al bands of insurgents sought refuge in the mountainous fas esses here, after the dispersion of their main body in W ford, and continued to harass the neighbouring countie until tranquillity was restored, partly by making terms wit their leaders, and partly by cutting roads and establishing ilitary posts through the interior of the country, which till hen had been nearly impassable.

he county forms one of the four great mountain groups of eland. The land rises from the valley of the Liffey an Dublin Bay on the north, by successive ridges, incre ing in height, and occasionally intersected by deep gle , to the middle of the county, whence it again subsides to e borders of Wexford and Carlow. The direction of the range is from north-east at Bray, to south-west, the ce ral part of the line being usually the most elevated, an the surface declining to the sea on the east, and the lev country of Kildare and Carlow on the west. Lugnaqu a, to the east of Baltinglas, is the most elevated point of e range: its summit is 3039 feet above the sea-level. T he north, on the verge of Dublin county, are the Butte Mountain, 1459, Kippure, 2473, and the Three-rock M ntain, 1763 feet high; more southerly, Djouce, 2384 fee and Sugar-loaf, 1126. In the centre are Thonalagee, 26 ; Comaderry, 2296; Lugduff, 2148; Knockreagh, 15 ; and Croghan, 2175. The glens form very striking an picturesque features of this romantic district, being de , narrow, and several of them densely covered with w l. The most celebrated are the Dargle, near the co ty of Dublin; Glencullen, Glencree, the Glen of the D ns, the Devil's Glen, Glenmalur, the Glen of Imail, an the Vale of Ovoca. The rivers are few and small, all ha ng their sources in the central group. The Liffey, wh h rises in Djouce Mountain, and after a circuitous co se through Kildare, discharging itself into Dublin Bay, is nown chiefly as having the metropolitan city on its ba s. The Slaney, which rises near Glendalough, is not na gable until it has traversed the greater part of Wexfo county. The Ovoca is formed by the junction of th Awenmore and Awenbeg at the meeting of the waters in he romantic Vale of Ovoca. It is afterwards joined by th Daragh or Aghrim from the west, and empties itself in St George's Channel at Arklow. The Vartrey, a small st m, falls into the sea north of Wicklow Head. Numerous la s lie in the valleys between the central mountain-ridges. T y are small, but generally surrounded by very pictu sque scenery. The most remarkable are Lough Bray, in lencree, near the borders of Dublin; Lough Dan, Lough T , Luggelagh, and the lakes of Glendalough. The last fo n an object of peculiar interest, from their romantic situ ion, the remains of ancient ecclesiastical structures in t r neighbourhood, and the popular legends connected w n them. The coast presents a succession of fine prospe s, but is much dreaded by mariners, in consequence of t sand-banks that skirt it. These are, the Kish Bank, each e emity of which is marked by a floating light; Bray B k, the Codling, South Ridge, Wicklow, and Arklow B ks. The southern extremity of the last named is also m ked by a floating light. The only harbours in this line o oast are those of Wicklow and Arklow, both fit only for s ll vessels. The projecting point of Wicklow Head is m ked by two fixed lights. A few creeks afford shelter fo fishing-craft. Herrings and round fish are taken off W klow Bank, where also oysters and lobsters are caught; b the business is carried on with so little spirit, owing, it is aid, to the want of capital, that fish is brought from D lin for sale. The state of the fisheries in 1836 was as ollows:

	No.	Tonnage.	Men.
Decked vessels	39	1174	156
Half-decked ditto	153	1425	858
Open sail-boats	57	—	246
Row-boats	14	—	38
Total of fishermen			1298

The western side of the county presents one of the great granite formations of Ireland, extending from Kingstown Harbour to the south-western extremity of the county. Each side is bordered by a range of clay-slate rock, passing into greenstone or a greenstone-slate. The rest of the county consists of clay-slate, graywacke, and graywacke-slate, interspersed in various places with small patches of granite, quartz-rock, and greenstone-trap protrusions, with whin-dykes. The eastern side of the granitic range abounds with metalliferous veins, while the western is totally destitute of them. Lead has been raised near Lough Dan, at Luganure in Comaderry Mountain, at Glendalough, and at Ballyfinshogue; copper at Ballymurtagh and elsewhere. The annual produce of the lead-mines now in operation is estimated at 2500 tons, valued at L.38,000; and of copper and lead in other mines at 12,500 tons, value L.35,000. The granite supplies inexhaustible quantities of stone for building and flagging. Slates for roofing are procured at Dunganstown and Carnew. The climate, though moist, is healthy; the lower lands near the sea produce the arbutus, myrtle, and laurestinus, which flourish in the open air, seldom requiring artificial protection during winter. The character of the soil is very various; near the sea, and along the banks of the larger rivers, it is rich, abounding with limestone, limestone-gravel, and marl. The mountainous tracts have generally a deep thick covering of heath and turf, based upon disintegrated granite. This part contains large tracts of bog. Along the verge of Dublin boundary, a substratum, lying within a few inches of the surface, forms a crust impenetrable to water, thus rendering the upper soil wholly unprofitable until this layer be broken up with the axe, for it resists the action of the spade or plough; after which, when blended with the subjacent clays, it forms a productive soil. Much of the natural timber with which the county was at a former period nearly covered, is still preserved, forming an important feature in the landscape; and young plantations are yearly rising around the mansions and villas with which this district, the chosen pleasure-ground of Ireland, is thickly studded.

The progress of the population, as far as it can be ascertained from authorities worthy of notice, is as follows:

Year.	Authority.	No. of Inhabitants.
1760	De Burgo	43,872
1792	Beaufort	58,000
1812	Parliamentary census	83,109
1821	Ditto	110,767
1831	Ditto	121,557

The latest of these returns gives an average of one inhabitant to every four acres. The return of the Commissioners of Public Instruction in 1834, which, being arranged according to dioceses instead of counties, cannot be deemed strictly accurate, gives a gross population of 118,661, of whom 25,005 were members of the established church, 322 Protestant dissenters, and 93,334 Roman Catholics. The number of children receiving instruction in the public schools at the under-named periods was,

	Males.	Females.	Sex not ascertained.	Total.
1821	5597	3108	—	8,705
1824–6	6377	4671	285	11,333
1836–7	1151	1012	—	2,163
1837–8	1232	1042	—	2,274
1838–9	1549	1351	—	2,900

The number of the children of each religious denomination, as stated in the return of 1824–6, being the only one in which this point is noticed, was, members of the established church, 3666; dissenters, 31; Roman Catholics, 7270; besides 366 whose religion could not be ascertained. The number of schools, according to the same return, was 258, of which forty-four, having 3526 pupils, were supported by grants of public money; thirty-eight, with 1619 pupils, by voluntary subscriptions; and 176, with 6188 pupils, wholly by the fees paid by the pupils.

The county is divided into the seven baronies of Arklow, Ballinacor, Newcastle, Rathdrum, Shillelagh, Upper and Lower Talbotstown. These are subdivided into fifty-eight parishes, of which forty-nine are in the diocese of Dublin, two in Ferns, and seven in Leighlin. The diocese of Glendalough, which anciently comprehended the greater part of the county, having been united to that of Dublin in 1497, has been so intimately amalgamated with it that their respective boundaries cannot now be ascertained. The county returned ten members to the Irish parliament, two for the county at large, and two each for the boroughs of Baltinglas, Blessington, Carysfort, and Wicklow. All the boroughs were disfranchised at the time of the Union, and those of Wicklow and Baltinglas are the only two to which corporate privileges are to be granted under the municipal corporation act. The number of electors was, in

Year.	No.	Year.	No.	Year.	No.
1831	1013	1834	1670	1837	1679
1832	695	1835	1670	1838	1679
1833	1566	1836	1679	1839	1380

The number of electors is to that of the inhabitants as one to eighty-eight, and to that of the heads of families as one to fifteen. The county is in the Leinster circuit. The assizes are held in the town of Wicklow, where the county court-house, prison, and infirmary, are built. General sessions of the peace are also held there and at Baltinglas. The local magistracy consists of a lieutenant, sixteen deputy-lieutenants, fifty-nine other unsalaried magistrates, and a stipendiary. Under these is a constabulary force, consisting of a county inspector, five sub-inspectors, six head constables, and 199 constables and sub-constables. There is a second infirmary at Baltinglas, and four fever-hospitals, with a number of dispensaries in different parts. Lunatics are sent to the district asylum in Dublin, into which twenty-two cases from this county are admissible; but several patients are still kept in the county prison. Baltinglas, Rathdrum, and Shillelagh, have been fixed on as sites for workhouses for unions under the poor-law act.

The rich low lands near the sea, and along the banks of the Slaney and Ovoca, are under tillage, all the operations of which are carried on according to the most approved systems. Much of the mountain district is adapted for pasturage, particularly for feeding a small breed of sheep, whose meat is much prized in the Dublin market. The mountain of Lugnaquilla has a fine sheep-walk on its summit. Lime and marl are the chief manures: the former is brought by sea from Howth to the districts near the coast; it is also drawn in large quantities from Carlow to the inland parts. Butter is made in large quantities in the dairies, which are generally attached to the farm-houses. The fences in the most highly improved districts are of white thorn; in other parts earthen mounds, and in the rocky mountainous heights dry stone-walls

The manufacture of flannels was here carried on extensively, and a market-house for their sale was erected at Rathdrum; but it has declined greatly, and the woollen manufacture is now nearly confined to the fabrication of friezes and coarse cloths for home-consumption. Some coarse linen is also wrought for the same purpose. But the county owes its wealth wholly to its agriculture. Most of the produce is sent to Dublin; but some is exported from Wicklow and Arklow, and the quantities are annually increasing. The annual average of the exports and imports through these places is estimated as follows:

	Exports.		Imports.	
	Tons.	L.	Tons.	L.
Wicklow	16,000	85,000	8,000	15,000
Arklow	900	8,500	4,000	6,500
Total	16,900	93,500	12,000	21,500

This is the only county in Ireland in which there is no banking establishment, either private or joint-stock; yet it is the most thriving in proportion to its population and extent of productive land. There are loan-societies in eight places: the sums in the hands of borrowers at the close of 1839 amounted to L.9315, the number of borrowers during the same year to 9100.

Though the high state of prosperity this county displays is mainly attributable to the well-directed efforts of agricultural industry, yet some portion of it must be allowed to arise from the number of men of landed property whom the extraordinary beauty of the country has induced to make it their chosen place of residence, thus heightening its natural advantages of scenery by the adventitious ornaments of splendid mansions and villas, surrounded by demesnes laid out in the most refined style. Two main lines of road conduct the stranger through it. The one on the eastern side, and mostly near the sea-coast, presents an almost uninterrupted succession of splendid prospects, through a highly cultivated country. Proceeding from the city of Dublin, through the Scalp, the lands of Powerscourt, the Dargle, the Glen of the Downs, Delgany, the Devil's Glen, Luggelagh, Glendalough, and the Vale of Ovoca, to Arklow, the eye finds nothing to rest upon but scenes of rural beauty. The other main road, along the western side, chiefly through the rich valley of the Slaney, presents a similar succession of scenery of a less romantic character. Even the intermediate space, though wholly composed of mountain tracts little capable of high cultivation, presents several wild landscapes of combined cliff and glen, to which an easy access is found through the military road already noticed.

The peasantry, notwithstanding the proximity of the metropolis, resembles that of the more remote agricultural districts in habits, dwellings, and mode of life; the chief article of food being the potato, and the fuel turf, though coal imported from England is in general use among the wealthier classes, especially near the sea.

There are several eromlechs still existing, and many raths. Ruins of monastic buildings are to be seen at Baltinglas, Wicklow, Rathdrum, and Glendalough or "the Glen of the Two Lakes," where there is a pillar-tower, and the remains of several places of religious worship, one of them being the cathedral of the ancient diocese, from which it has acquired the name of "the Seven Churches." It had been the site of a city, the metropolis of the sept of the O'Tooles, and is now a place of great resort for visitors, from its picturesque scenery. Several castles were built in this county by the English, the sites of most of which can still be ascertained by what is left of their structures.

Wicklow, the assize-town, is built on an elevated spot projecting into the sea near the mouth of the Vartrey. It was originally the site of a castle erected by Maurice Fitzgerald, and was long maintained as a post of importance, under the superintendence of a constable. The town is small and irregularly built, owing most of its support to the assizes and sessions. It was a borough by prescription, but its corporate rights were confirmed by a charter of James I., granted in 1613, to be enjoyed under a portreeve, burgesses, and freemen, who had a right of exemp on from harbour-dues, and of pasturage on the com-mo The corporate landed property is about 300 acres. Th portreeve held a weekly court for the recovery of debts to t amount of five marks. By the municipal corporation act, e old corporation has been dissolved, and, under cer-tain conditions, power is to be given to create a new one, styl “ the portreeve, free burgesses, and commonalty of the own of Wicklow.” There is a Saturday market, and fou airs annually. Races are held every year at the Mur-ragh a border of dry sandy land, extending for several mil along the sea-shore to the north of the town, forming a p insula, which encloses a long narrow basin, in which ves s drawing less than eight feet of water can enter at spri g tides. The population in 1821 amounted to 2146, and n 1831 to 2472. The population of the other towns hav g each upwards of 1000 inhabitants was, in 1831, as foll s: Bray, 3656; Arklow, 4383; Baltinglas, 1699; and Ra drum, 1054. (C. P.)

ICKWAR, a small market town of the county of Glou-cest r, seventeen miles from Bristol and 111 from London. It i n the hundred of Grumbald's Ash, and was formerly a pla of more importance than it is at present. There is a spa ous church with a lofty tower, and a grammar-school enc wed by a native of the name of Hosea. It has a market on ednesday. The population amounted in 1821 to 919, an n 1831 to 972.

IDDIN, a city of Turkey in Europe, the capital of the pro nce of the same name. It stands on the river Danube, an s one of the strongest fortifications of the empire. In the ver opposite to it is an island, also covered with strong mil ry works. It is the seat of a Greek bishop, has nume-rou mosques, and, it is said, 25,000 inhabitants, who carry on sheries on the Danube, and considerable trade with the neighbours in the Austrian territories.

IELICZKA, a city of the Austrian kingdom of Gallicia, in e circle of Bochnia. It is distant from the independent cit of Kracow about seven miles. It contains 360 houses, wit 3700 inhabitants, who are chiefly employed or con-ne d with the celebrated rock-salt mines which exist at thi lace, and which have been extensively worked for many ag The mine is in a vast mountain, and the extent of th alt is not ascertained. On the top of the mountain is a s ft, and at the bottom an arched passage, both of which lea through numerous arched galleries, formed by removing bl ks of salt. In the mine is an excavated lofty chapel, in wh h mass is celebrated, and an extensive saloon, with other ap ments, all cut out of the solid mass of salt. The mine is ite dry, but within it is a clear subterranean lake, with a l at upon it. Though, ever since the year 1276, the salt ha been drawn forth in copious quantities, there is abun-da e to be taken away without any additional labour. It be ngs to the government, which derives a revenue from it. The expense of hewing it with the pick-axe, and of dr ing it out of the mine, is calculated to be from 12s. to 14 per ton, and the price at which it is sold is about 20s., th leaving a profit to the government. The demand is re ained on the side of Prussia, because the English salt co es in competition with it. It is however extensively sol in the crude state in the Russian and Polish provinces, wh e it is dissolved, and refined for domestic use. That us in the Austrian states is refined at Wieliczka. This ro -salt is mostly of a gray colour, but some of it is of a gr nish hue: both kinds are very hard and very dry.

IESBADEN, one of the provinces into which the du y of Nassau in Germany is divided. It is on the Rh e, and is bounded by other provinces of the duchy on ev y part except the south-east, where it touches Hesse-D mstadt. It comprehends one city, two market-towns, tw ve villages, 2272 houses, and 18,922 inhabitants. A pa is hilly, but much of it a rich level country. The si of the hills are covered with highly productive vineyards, and their summits with rich forests. The corn grown is much more than sufficient for its own population.

WIESBADEN, a city of the duchy of Nassau, and now its capital, where the states assemble, and in which the chief courts of justice are held. It is an open place, having only the ruins of walls at the ancient parts of it. The new town is an elegant mass of buildings, both for private residences and public purposes. The old city is ill built. Both together contain 8970 inhabitants, who are regular residents; but in the summer months the number of temporary visitors is greater than the permanent population. They are chiefly attracted by the reputation of the warm baths, but many also by the pleasures and accommodations attainable in a more favourable degree than at any of the other German watering-places. The assembly-rooms and the hotels are striking objects. There is a Catholic, a Lutheran, and a Calvinist church, and a ducal palace. The adjacent country is often picturesque, and, from the good state of the roads, the excursions are agreeable. The town contains a variety of manufactures of what may be called fancy articles and luxuries, and, on the whole, has many attractions.

WIGAN, a large town of the county of Lancaster, in the hundred of West Derby, 200 miles from London. It stands on the small river Douglas; is a corporation under a mayor, ten aldermen, and thirty councillors; and returns two members to the House of Commons. Being an ancient town, some parts of it are ill built; but of late years, from the extension of its trade, great improvements as well as additions have been made. The church is a stately edifice, with a tower containing eight bells; and there are chapels of ease and several dissenting places of worship. The living of the parish is one of the most valuable in the kingdom, and the incumbent is lord of the manor. Wigan has been long celebrated for its manufactures, which formerly consisted of checks and other linens, but of late the cotton trade has been extended to it, and is flourishing. There is a well-attended market on Friday. The population amounted in 1821 to 17,716, and in 1831 to 20,774 within the town; but the whole parish, which comprehends thirteen townships and chapelries, in 1831 contained 44,780 inhabitants.

WIGHT, ISLE OF. This island, on the southern coast of England, in the British channel, is for most purposes a portion of the county of Southampton, or Hampshire. It is separated from it by a channel varying in breadth from two to six miles. In this channel, though it contains no harbour of importance, there are many places of perfect security, where ships may ride at anchor. The best of these is Spithead, the great rendezvous of the British fleet in time of war; but in most other parts the ground is good, and the vessels are well sheltered from storms. The entrance to this arm of the sea from the west is by the Needles, some lofty rocks, five in number; but two of them are nearly covered at high water. These obtained their name from one which rose to the height of 120 feet, resembling that implement of industry. It was undermined by the waves, and at length, in 1764, fell down with a concussion that was felt at the distance of many miles. The group has now an impressive appearance, especially when the agitated sea breaks on their sides. The passage between them is generally free from danger.

The island is divided into two hundreds, indicated by the principal river, and called East and West Medina. East Medina comprehends fourteen parishes, and West Medina sixteen. The whole land is calculated to be 105,000 acres, of which 75,000 are under the plough, 20,000 are devoted to pasture, and the remainder is either waste or woods, or the sites of towns or villages, or occupied by roads and rivers. It is said to have been formerly covered with woods, but to have been in a great measure denuded by its vicinity to Portsmouth, and the great demand of that naval arsenal for timber.

Wight, Isle of.

The face of the country may be rather described as undulating than as hilly, though there is a range of hills, or rather downs, running from east to west through the island, with a few points of considerable elevation. There is a great variety of rural scenery, adorned with a great diversity of foliage; and though there are few or no woods, yet, as the fields are enclosed within hedge-rows, among which fine trees, and especially stately elms, grow most luxuriantly, these, added to the beauty of the verdant fields, present to the eye of the traveller a succession of most pleasing prospects. The two sides of the island present each a peculiar character. The northern side is marked by every thing that is rich, lovely, and picturesque; the southern, or the part called the *Back of the Island*, abounds in bold wild rocks, precipitous projections, ravines, fearful chasms, and other features of the imposing, and a few even of the sublime. In some parts these opposite characters are greatly mingled. There is a peculiar scenery on the south side of the island, which is so striking to all strangers as to require a special notice. It is a continued sinking of a tract of land, about seven miles in length, and from a half to a quarter of a mile in breadth. This singular district consists of a series of terraces, formed by fragments of rocks, chalk, and sandstone, which have been detached from the cliffs and hills above, and deposited upon a substratum of white marl. This whole *undercliff*, for such is its common name, is completely sheltered from the north, north-west, and west winds, by the range of lofty downs or hills of chalk or sandstone which rise boldly from the upper termination of these terraces, on elevations varying from four to six and seven hundred feet in height. The two extremities of the range are indeed higher, as St Boniface Down is 800 feet above the level of the sea, and St Catherine's Hill on the west nearly 900 feet. The protection afforded by this mountain barrier is greatly increased by the very singular and striking abruptness with which it terminates on its southern aspect. This in many places consists of the bare perpendicular rock of sandstone; in others of chalk, assuming its characteristic rounded form, covered with a fine turf and underwood.

The chief industry of the island is applied to its agriculture. The soil is for the most part clay, with a mixture of loam, and in some parts of a very cold and tenacious kind; it is however generally fertile, and the meadows produce very great crops of hay. The grain sown, whether wheat, barley, or oats, yields good crops, and affords more corn than is needed for home consumption; and hence much flour is exported. As the harvest is ready to be gathered earlier by a few weeks on the island than in the neighbouring counties of Dorset and Hants, the labourers from them flock to reap the corn, and return sufficiently early to reach their own homes, and there also to assist in the harvest-work. The manures of the island, besides what the farm-yards and stables supply, consist of sea-weed, marl, and lime, the latter of which is copiously supplied from the chain of calcareous elevations which has been already noticed. There is little foreign trade, though a great number of ships of all nations have intercourse with the towns of Cowes and Ryde. Vessels from America, bound in search of a market, especially during war, commonly touch at the former place to ascertain the state of the different markets, and to communicate with London for intelligence to direct their destination. Between the Isle of Wight and Portsmouth is the great rendezvous of outward-bound ships from London; and in war large fleets of East and West India ships are there collected to wait for convoy. The demand for fresh sea-stores is consequently very great, and the supply of it very advantageous. Fowls, live sheep, milch goats, milch cows, pigs, and potatoes, are cheaper than in the Thames; and most outward-bound vessels trust to obtaining such provisions at the anchorage of the Motherbank or Spithead. During the long hostilities, by this description of trade the wealth of the island increased very rapidly; and though, since the return of peace, these sources of prosperity have been much curtailed, yet others have opened or been extended. Ryde, as well as Cowes and several other spots, have become places of great resort for sea-bathing, and have gradually acquired all the accommodations to be found in the more ancient bathing places on the shore. Of late, too, it has become the point of union for the vessels and members of the *Royal Yacht Club*, who have built a house at Cowes, and made that place the resort of some of the most distinguished persons who take pleasure in maritime adventures and expeditions. The population of the island at the enumeration of 1831 was found to consist of 17,205 males, and 18,226 females. The chief town, Newport, at that period, contained 4081 inhabitants. The other towns are, Brading, with 2277 persons; Cowes, in the parish of Northwood, the population of which parish was 4491; and Ryde, in the parish of Newchurch, whose inhabitants were 4928.

The town of Newport returns two members to the House of Commons, as before the reform act, by which the boroughs of Newton and Yarmouth were disfranchised. The freeholders of the island used to vote for the members of the county of Hampshire, but they now elect one member for the island.

WIGTON, a county situated at the south-west corner of Scotland, is bounded on the west by the Irish Channel, on the north by Ayrshire, on the east by Wigton Bay and the river Cree, and on the south by the Irish Sea. It is consequently bounded by water on all sides except the north. No part of the county is above thirteen miles from the sea. Its length from east to west is thirty-four miles; its mean breadth is twenty-four. It is divided into three districts, the Machers (flat country), lying between Wigton and Luce Bays; the Rhinns (peninsula), which comprehends the portion lying west of a line drawn between Luce Bay and Lochryan; and the Moors, which include the remainder, being more than a third of the whole county.

The following table shews the population of the county at different dates.

1755.	1801.	1831.		
		Males.	Females.	Total.
16,466	22,918	17,078......	19,180......	36,258

The increase in the number of the inhabitants between 1755 and 1831 has been 19,792; in other words, the population has been considerably more than doubled. The number of square miles in the county being 459, there are seventy-nine inhabitants to each square mile; the average of the whole of Scotland being about eighty. The number of families in 1831 was 7514; of inhabited houses, 6404; the number of persons to each family being 4·825; to each house, 5·661.

Wigton being a remote county, and having little intercourse with any other portion of the kingdom, the greater part of the present inhabitants can trace their descent through many generations; the only exception being in regard to Irish settlers, who are somewhat numerous, particularly in the towns and villages, and who, including their families, form about a fifth of the entire population of the county. The Gallovidians are of Celtic origin; and so late as the time of Queen Mary, Gaelic was their vernacular language. The surnames, which prevailed in the county four and five centuries ago, and even at a more remote period, still predominate, such as Macdowall, Mackerlie, Maculloch, Mackie, Macklellan, Macguffie, Mackinnell, Macgowan, Macgeoch, Macgill, Macracken, Macnish, Adair, Dunbar, Agnew, Stewart, Gordon, Hannay, Broadfoot, Donnan, Milroy, Milwain. While old names and old families thus obtain, very few new ones, except so far as emigration from Ireland prevails, have been introduced. But not a few of the oldest and best families were originally of

Iri descent. From these circumstances it may be presu ed, what is really the case, that the feudal feeling exists m e strongly and generally in Wigtonshire than in any ot r county in the south of Scotland. Superstitious obse ances and traditionary legends abound. Belief in wi hes, in ghosts, in lucky and unlucky days, and other simi r hereditary notions, are common throughout the county, pa cularly in the more remote and thinly inhabited paris es.

oor-rates are unknown in this county, with the exceptio of one parish. Out of the whole population, there are on about 700 receiving parochial aid; that is, only one pe on in fifty-two is a pauper, being less than a third of the av age of England. The aggregate annual amount distribu d among these 700 persons is about L.1375, being rath less than L.2 for each pauper, or at the extraordinary lo rate of 6d. per head of population. The lowness of th rate will be better appreciated when we state, that, previ sly to the new poor-law amendment act in 1834, the av age burden in England was thirty-three times greater.

he climate, though characterized by considerable variati s, and though, on the whole, subject to moisture, is rega ed as salubrious. The instances of persons being able to ollow their usual occupations, even at the age of eighty, ar common. Alexander Credie, a native of the Machers, di in 1824, at the venerable age of 108.

he physical appearance of Wigtonshire is not varied. E n the district called the Moors is not distinguished by an considerable hills or eminences; and it has been rem ked that there is no county in Scotland that rises so lit e above the level of the sea. Nor are there any impo ant rivers; at least none of them is navigable except th Cree and the Bladenoch, both of which flow into Wigto Bay; the former being navigable for six miles, the latte for two. But, though not possessed of large and navi ble rivers, this county abounds with spacious bays and h bours, namely, Lochryan on the north-west, which st tches about nine miles inland till it reaches Stranraer, w re it terminates, its breadth varying from two to four m s; Luce Bay on the south, stretching inward about fi en miles, its breadth regularly graduating from twenty m s at its mouth; and Wigton Bay, varying from eight m s in width, till it reaches the Cree, a distance of about te miles. These two latter bays form two remarkable pr montories, the Borough Head on the south-east, and th Mull of Galloway on the south-west, the two most so herly points in Scotland; the latter being about one mile an a half south of the former. The most important harbo rs are Carty on the Cree, Wigton on the Bladenoch, G lieston on Wigton Bay, Isle of Whithorn near the Boro gh Head, Glenluce and Sandhead on Luce Bay, Port L an and Portpatrick on the Irish Channel, and Stranra and Cairnryan on Lochryan. The fresh-water lochs, th gh numerous, only occupy an aggregate of seven and a ha square miles.

he county abounds with towns and villages along the co t, but none of them is of great importance. Of Wigto Whithorn, and Stranraer, a separate account has been gi en. Portpatrick, with a population of 1010, is situated o the Irish Channel, nearly opposite to Donaghadee, betw en which places two government mail steamers ply da y. The harbour is undergoing great repairs, and two pi s are erecting by act of parliament; the estimated exp se is L.150,000. Glenluce, population 821, is situa d within 500 yards of the river Luce, and at the head o the bay of that name. Newton-Stewart, population 2 1, lies on the banks of the Cree, eight miles north of Wigto Garlieston, population 587, and the Isle of Whithorn, p ulation 697, are both situated on the west coast of Wigton B , the latter being the port of Whithorn. Port-William, p ulation 510, on Luce Bay, possesses a good harbour.

Wigton.

The soil of the three districts into which Wigtonshire is divided, the Rhinns, the Machers, and the Moors, is very different. The soil of the first two is for the most part a hazelly loam, dry, and well adapted for turnip husbandry; but in the barony of Baldoon, which is regarded as the Carse of Gowrie of the south of Scotland, and in the low-lying lands between Wigton and Newton-Stewart, there is a great extent (above 25,000 acres) of rich alluvial soil; while the remaining district (the Moors) is bleak and barren, chiefly devoted to pasture, with few spots fit for tillage, great portions of it being mossy land, partially covered with water, such as the *flow* of Glenluce. The most approved system of agriculture has been everywhere introduced, particularly in the Rhinns and Machers. Of the relative proportions of land in crop and in pasture, a correct idea may be formed from the fact, that out of 288,960 English acres which the county contains, 101,136, or about thirty-five per cent., are under cultivation; while 187,824, or about sixty-five per cent., are in pasture, including 4265 under wood. Property in land in Wigtonshire is very little subdivided. There are four or five large proprietors whose united estates embrace about the half of the county. There are comparatively few proprietors whose estates are under L.500. The average rent of land in 1810 was 8s. 6d. per acre; the aggregate rent in 1837 was L.175,000, being about 12s. an acre. The valued rental of the county is L.67,642 Scotish, old valuation. Leases generally extend to nineteen years. Two agricultural societies have long existed in the county; and the class of farmers, in point of general intelligence and professional skill, is highly respectable.

Wigtonshire is devoid of mineral wealth, nor can it be said to possess any considerable manufactures. There is a whiskey distillery at the Bridge of Bladenoch, within a mile of Wigton, which consumes yearly about 16,000 bushels of barley, and gives employment to between twenty and thirty persons. A woollen manufactory was established in the parish of Kirkowan in 1822, which in 1838 employed thirty-nine hands. There are several small breweries scattered throughout the county. The salmon and white fishery is carried on at the mouths of some of the rivers and along various places on the coast, but to no very considerable extent. Exclusively of fishing boats and steamers, the county has ninety-six vessels; tonnage, 5371.

But Wigtonshire, from the general progress of the arts of peace, now enjoys advantages unknown there even a few years ago. Remote as is her situation, she is reaping all the advantages which steam-navigation is calculated to confer. Two steam-boats regularly ply between her leading ports and Whitehaven and Liverpool, so that a ready and advantageous market is opened for her sheep, black cattle, and agricultural produce. A farmer can now send his stock and his corn to Liverpool, and get them disposed of in the shortest time, at the market price, and for ready money. Formerly the case was quite otherwise; corn-dealers and drovers travelled the country, buying grain and cattle, with the view of shipping them to an English market. Their purchases were seldom if ever made with cash: on the contrary, it was almost the invariable practice to grant bills for payment, at four or six months. These were not always men of capital, and the business which they followed was, from its very nature, a most precarious one; so that, in proportion to their numbers, a greater proportion of such provincial dealers is known to have become bankrupt than of any other class of men. Hence the great risk and eventual losses to which (as is known to the present writer) the farmers in Wigtonshire were continually exposed, and the general bankruptcy and distress that periodically ensued. In addition to the steamers which regularly ply between Wigtonshire and England, there are two steam-boats which sail weekly between Stranraer and Glasgow, so that the inhabitants of this remote county have

Wigton.

now the ready and frequent command of the best markets both in Scotland and England, either for buying or selling. We have already referred to the two government steamers that daily ply between Portpatrick and Donaghadee. But while steam-navigation has been productive of such important advantages as we have described, it has been attended with other results, which, though favourable in a national point of view, are unfavourable to the district. The traffic and travelling that had formerly prevailed between Ireland and England *via* Portpatrick, through Galloway, have been in a great measure turned into a new channel, and this county has in consequence proportionally suffered. There is now very little travelling by this route; and the steamers plying from almost every Irish port to Liverpool or Holyhead, engross almost the whole of the travelling of which Galloway formerly enjoyed the advantage. Nor is this all; the importation of Irish horses and black cattle at Portpatrick has diminished to a similar extent. It appears from the New Statistical Account of Scotland, No. 22, p. 153, that whereas the number of such stock imported at Portpatrick was 17,275 in 1790, and 20,000 in 1812; it was only 1080 in 1837. We may here mention, that the mail-coach was first introduced into Galloway in 1804, and that it has since continued to run daily between Dumfries and Portpatrick. There is not, and never was, an opposition coach in Wigtonshire.

This county is distinguished for the antiquity and number of its religious houses. The oldest church built of stone in Scotland was situated at Whithorn, as mentioned in our account of that borough; and in the 12th century a monastery of the Premonstratensian order was founded there by Fergus, Lord of Galloway. The same individual established another abbey of the same order called Saulseat (*Sedes Animarum*) near Stranraer. Roland, grandson of Fergus, founded, in 1190, the abbey of Glenluce, for monks of the Cistertian order; and the abbey of Wigton was established in 1262, for Black Friars, by Lady Dervorgille of Galloway. (Murray's Literary History of Galloway, pp. 12, 24, 26, 30, 2d edit. Edinb. 1822, 8vo.) There are also the remains of numerous subsidiary churches and chapels, built either for the use of some baron, or for the advantage of the remote inhabitants of a large parish. At the Reformation, Wigtonshire contained twenty-one parish churches, exclusive of the various subsidiary chapels referred to. Parishes have now been more judiciously arranged: in some cases three have been united into one; and though three *new* parishes have been erected, the total number is reduced to seventeen.

Several eminent characters were natives of this county, namely, St Ninian, who founded at Leucophibia, now Whithorn, the bishopric of Candida Casa, or Galloway, and who died in the fifth century; Gavin Dunbar, tutor to James V. and afterwards archbishop of Glasgow, and lord chancellor of the kingdom; Sir Patrick Vans, ambassador to Denmark in the time of James VI., and a lord of session; Patrick Hannay the poet, son to Hannay of Sorbie; Andrew Macdowall, Lord Bankton, author of Institutes of the Law of Scotland; Dr Macgill of Ayr, and Dr Mackenzie of Portpatrick, two eminent divines, the latter author of Ocean, Stella, and other poems; and Major Stewart Maxwell, author of the Battle of the Bridge. Some distinguished men, both laymen and clergymen, such as Archbishop Beaton, prior of Whithorn; Bishop Cowper; Lord Stair, the famous lawyer; his son, the first earl of Stair; and grandson, Marshal Stair, were connected with the county, either by office or the possession of property.

The history of Wigtonshire, as part of Galloway, is not uninteresting. The aborigines, who were of Celtic origin, were the *Novantes*; their chief towns *Leucophibia*, the present Whithorn, and *Rerigonium*, on the *Rerigonius Sinus*, or Lochryan. The Mull of Galloway was called *Promontorium Novantium*. Galloway was invaded by the Romans. On the retirement (448) of that warlike people, it was successively overrun by the Anglo-Saxons of Northumbria, and by the Picts. But notwithstanding their falling successively under the dominion of these various people, the original Celtic inhabitants of Galloway were never entirely displaced; their characteristic customs and manners continued to predominate, and remains of such may be traced even at this day. They were distinguished for daring heroism and intrepidity, insomuch that they obtained the appellation of the wild Scots of Galloway, and obtained from the Scotish kings the privilege of forming the van in every battle at which they were present. The province was for upwards of a century an independent province, governed by its own princes or lords. Alan, who died in 1234, was the last of the ancient Lords of Galloway. John Balliol was grandson of Alan by his daughter Lady Dervorgille, and thus possessed extensive estates both in Wigtonshire and the stewartry of Kirkcudbright. The county of Wigton, with the title of earl, was conferred (1341) by David II. on Sir Malcolm Fleming; but Fleming, amid the distraction of the times, was obliged, in 1372, to dispose of his estates (though he retained the title) to Archibald Douglas. From this date the Douglases reigned supreme till their forfeiture in 1453. The county was then parcelled out among different families, many of which still remain; and the Agnews of Lochnaw were created heritable sheriffs. This office remained in their family till the abolition of hereditary jurisdictions in 1747, with the exception of seventeen years previous to the revolution, when Graham of Claverhouse and his brother Colonel David Graham were appointed joint-sheriffs. (Chalmers's Caledonia, vol. i. *passim*; Murray, *ut supra*; New Stat. Acc. of Scotland, sec. Wigtonshire.) (c. l.)

Wigton, a royal borough, and the capital of the county of the same name, is situated on a detached eminence about 200 feet above the level of the sea, at the confluence of the Bladenoch with Wigton Bay, and 105 miles south-south-west from Edinburgh. It consists mainly of one street about 600 yards in length, and, though narrow at the two extremities, so wide in the centre as to admit of a square containing a bowling-green and spacious walks. The houses are well built and substantial; some of them are old, and the town altogether has a respectable and venerable appearance. It can boast, however, neither of trade nor manufactures. The harbour is within a quarter of a mile of the borough, and the dues are let for the small sum of L.26 per annum. There are fourteen vessels belonging to Wigton, the aggregate tonnage being about 880. A steam-boat plies between this port and Whitehaven and Liverpool once a fortnight during the year. A branch bank has been established here since 1784. A packet plies daily between Wigton and Creetown, on the opposite side of the bay, a distance of about four miles. The population, which has long been nearly stationary, was 1837 in 1831. In addition to the parish church, there is a dissenting chapel; the only other public building is the town-hall, which also includes a jail. Wigton was created a royal borough in the time of David II. The number of councillors is eighteen. The municipal revenue is about L.350. The borough unites with Whithorn, Stranraer, and New Galloway in sending a representative to the House of Commons. The number of registered voters in Wigton in 1840-1 was 102.

The town can boast of great antiquity. The first church here was consecrated to St Machute, an obscure saint, who died in 554. It originally belonged to the priory of Whithorn, but was afterwards a free rectory, the minister of it being a member of the chapter of the cathedral. The eastern gate of the present parish church is supposed to have formed part of St Machute's church. In the churchyard there are monuments to the memory of several martyrs who suffered during the reigns of Charles II. and James VII particularly those in honour of two female martyrs, who ere drowned in the Bladenoch in 1685. Wigton was the e of a monastery, founded in 1267, for Dominican friars, by ervorgille, daughter of Alan, the last lord of Galloway, and other of John Balliol the Scottish king. This monastery ever attained to eminence, and no remains of its ruins can ow be traced. This latter remark is also applicable to the astle of Wigton, once a place of great importance. It fell to the hands of Edward I. in 1291. (C. I.)

V GTON, a market-town of the county of Cumberland. It i n the ward of Cumberland, twelve miles from Carlisle, and 05 miles from London, in the vicinity of the ruins of an cient Roman work called *Caer Leol.* The market is on uesday. The population amounted in 1821 to 4056, and n 1831 to 4885; but the parish comprehends three oth townships, and in 1831 contained 6501 inhabitants.

ILBERFORCE Cape, a rocky promontory on the nor coast of New Holland, at the west entrance into the Gu of Carpentaria. Long. 136. 33. E. Lat. 11. 52. S.

ILBERFORCE, William, was born at Hull on the 24t of August 1759. His father, a merchant of that town, tra d his descent from an ancient family which had long pos ssed a large estate at Wilberfoss, in the east riding of e county of York. The father of Wilberforce died be e his son had completed his tenth year, and he was the transferred to the care of a paternal uncle, on whose de n the ample patrimony which he inherited from his fat r was largely increased. His uncle's wife was a great ad rer of Whitefield's preaching; and through her instrume ality his early years were not suffered to pass away wi out permanent impressions of religion. From school, W erforce was transferred, at the age of seventeen, to St Jo 's College, Cambridge. On leaving college, he imme ately entered upon active life. At the general electio of 1780, when he had just completed his twenty-first ye , he was returned to the House of Commons for his na e town, and soon found his way into all fashionable an political society. At Cambridge he had formed an ac aintance with Mr Pitt, which speedily ripened into an af tionate union, that none of the vicissitudes of political lif could afterwards dissolve. In the autumn of 1783, W erforce set out with Pitt for a tour in France; and on hi return to England he gave his friend most efficient suppo in his memorable struggle against the majority of the H se of Commons. At a public meeting held in the C tle Yard at York in March 1784, he attacked the measu s of the coalition with such eloquence and success that h was immediately nominated as a candidate for the represe ation of Yorkshire; and so strongly did the current of p ular opinion flow in his favour, that in spite of the h erto predominant influence of the great Whig families o hat county, his opponents gave up the contest without v turing to the poll. In the autumn of 1784, accompanie by some female relations, and by the celebrated Isaac M ner, dean of Carlisle, he undertook a journey to the c tinent. This excursion forms a memorable era in his li ; for, through the influence of Milner, his early impressi ns of religion, which had been greatly dissipated, were r ived, and a deep and fervent piety now took entire poss sion of his mind, and regulated the whole of his future c duct. In the year 1787, he was much occupied in conc ting measures for the reformation of manners; and about t same time he became the founder of an association for t discouragement of vice. It was in this year also that M Wilberforce entered upon his labours in that great cause w h which his name is unalterably associated, the abolit n of the slave-trade. To that cause he now dedicated his d s and his nights, even to his closing hours. It was in 1 89 that he first proposed the abolition of the slave-t de to the House of Commons; and the zeal, the patience, the talents, and courage which he displayed during the many dispiriting delays and formidable difficulties which he had to encounter before the cause of justice and humanity finally triumphed, are above all praise. In 1797, he published his celebrated work on Practical Christianity, which met with such remarkable success that within half a year five editions had been called for. Not less than fifty large editions have now been published in England and America; and it has been translated into the French, Italian, Spanish, Dutch, and German languages. Ecclesiastics of every class, from old John Newton to the archbishop of Canterbury, welcomed it with the loudest applause; and Burke spent much of the two last days of his life in reading it, and said that he derived much comfort from its perusal. It would be difficult to overrate the influence of this work in stemming the tide of irreligion and nominal Christianity, especially among the higher classes of society, and in giving a powerful impulse to that warmer and more earnest piety which has happily distinguished the last half-century. In 1807, after twenty years of anxiety and unremitting labour, Mr Wilberforce had the high gratification of seeing the slave-trade abolished, and that stain on our national character for ever obliterated. During the debate on the second reading of the abolition bill, when Sir Samuel Romilly entreated the young members of parliament to let this day's event be a lesson to them how much the rewards of virtue exceeded those of ambition, and then contrasted the feelings of the emperor of the French in all his greatness, with those of that honourable individual who would this day lay his head upon his pillow, and remember that the slave-trade was no more, the whole house, surprised into forgetfulness of its ordinary habits, burst forth into acclamations of applause; a tribute of approbation "such as was scarcely ever before given," says Bishop Porteus, "to any man sitting in his place in either house of parliament." Though Mr Wilberforce survived the abolition of the slave-trade for more than a quarter of a century, he quitted the House of Commons in the year 1825. He had resigned the representation of Yorkshire in 1812, on account of his declining health; and during the remainder of his parliamentary career he was returned for the borough of Bramber. The interval between the passing of the abolition bill and the close of his parliamentary labours was devoted to a ceaseless watchfulness over the interests of the African race. He lived to witness the consummation of the struggle for the abolition of slavery throughout the British dominions; and the last public information he received was, that his country was willing to redeem itself from the national disgrace at any sacrifice. He died July 27, 1833, when within a month of completing his seventy-fourth year, and was interred in Westminster Abbey, near the tombs of Pitt, Fox, and Canning. "Few persons," says Lord Brougham, "have either reached a higher and more enviable place in the esteem of their fellow-creatures, or have better deserved the place they had gained, than William Wilberforce." His immense influence was no doubt greatly owing to the homage paid to his personal character, but he possessed many other qualifications which must of themselves have raised him to great eminence. As a public speaker, he enjoyed great and well-merited celebrity. His eloquence, though for the most part of the persuasive and pathetic kind, was also occasionally bold and impassioned; and he possessed an extraordinary power of sarcasm, which, however, the singular kindness and gentleness of his disposition rarely permitted him to employ. Sir Samuel Romilly esteemed him "the most efficient speaker in the House of Commons;" and Pitt himself said repeatedly, "of all the men I ever knew, Wilberforce has the greatest natural eloquence." In politics, Mr Wilberforce uniformly acted on independent principles, and steadily refused all office through his whole life. Though strongly attached to Pitt, both by political opinions and by the ties of friendship, he pursued his course wholly unfettered by party connection; and he differed with his illustrious friend upon the two most critical emergencies of his life, the question of peace with France in 1795, and the impeachment of Lord Melville ten years later. Mr Wilberforce married, in the year 1797, Miss Barbara Spooner, daughter of a banker of that name in Birmingham. By this lady he had six children, of whom four sons still survive, his two daughters having died before their father. (B. Q.)

WILEIKA, a circle of the Russian government of Minsk, extending in north latitude from 54° 24′ to 54° 58′, and in east longitude from 26° 7′ to 28° 22′. In the west part it is filled with sandy heaths, and in the east with morasses. Between these are extensive woods, with portions among them of land highly productive of corn, hemp, and flax. Several rivers have their sources within the circle, the most considerable of which are the Wilia and the Beresina. A canal of thirty miles in length has been constructed, which unites the river Duna with the Beresina; but, from want of a suffieient head of water, it is only navigable in the spring of the year, even by small barks. The capital of the circle is of the same name, on the river Wilia. It has nothing remarkable, and contains scarcely more than 1000 inhabitants. It is 554 miles from St Petersburg. Long. 26. 40. E. Lat. 54. 35. 30. N.

WILKIE, William, the author of the Epigoniad, was born in the parish of Dalmeny and county of Linlithgow on the 5th of October 1721. His father was a small farmer, and was not very fortunate in his worldly affairs. He however gave his son a liberal education, the early part of which he received at Dalmeny school; and at the age of thirteen he was sent to the university of Edinburgh, where he was soon distinguished as a young man of genius. Among his fellow-students were Dr Robertson the historian, Mr Home the poet, and some other eminent literary characters. In the course of his education he also became acquainted with David Hume and Adam Ferguson. Before he completed his studies at the university, his father died, leaving him only the stock and unexpired lease of his farm, with the care of three sisters, one of whom being afterwards married to an experienced farmer, Wilkie availed himself of his practical knowledge. He formed a system of farming which fully answered his own expectations, and secured to him the approbation of all his neighbours. After becoming a licentiate of the church of Scotland, he still continued his former mode of living, cultivating his farm, reading the classics, and occasionally preaching for the ministers in his neighbourhood. In 1753, he was presented to the living of Ratho by the earl of Lauderdale, who was sensible of his worth, and admired his genius. The duties of his new office he discharged with fidelity, and was celebrated for his impressive mode of preaching, while he did not neglect the amusements of husbandry, and the study of polite literature. In 1757 he published, at Edinburgh, "The Epigoniad, a Poem, in nine books," which is said to have been the result of fourteen years study. Hume endeavoured to promote its success by addressing a commendatory letter to the editor of the Critical Review. A second edition of the poem was published at London in 1769. In 1759 Wilkie was elected professor of natural philosophy in the university of St Andrews. His whole fortune, when he removed to this place, did not exceed L.200, which he laid out in the purchase of a few acres of land in the vicinity of the city. He lived at St Andrews in the same studious and retired manner as he had done at Ratho. In 1766 the university conferred upon him the degree of D. D. He ended his poetical career by publishing a volume of Fables. Lond. 1768, 8vo. After a lingering illness, he died on the 10th of October 1772, having only completed the fifty-first year of his age. The personal character of Dr Wilkie exhibited many singularities; but the very distinguished individuals with whom he was acquainted were all disposed to regard him as a man of talents as well as learning. The subject of his Epigoniad was injudiciously chosen; nor is it surprising that he did not acquire the reputation of a great epic poet.

WILKINS, John, an eminent philosopher and divine, the son of Walter Wilkins, a goldsmith of Oxford, was born in 1614, at Fawsley, near Daventry in Northamptonshire, in the house of his maternal grandfather, John Dod, a non-conformist. After being trained in a private school at Oxford, he was entered of New Inn Hall in 1627, but was not long afterwards removed to Magdalen Hall, where he took his degrees in arts. On receiving holy orders, he became chaplain to Lord Say, and afterwards to Charles Count Palatine of the Rhine. To the favour of this prince his knowledge of mathematics was a strong recommendation. At the age of twenty-four he published "The Discovery of a New World; or, a Discourse tending to prove that 'tis probable there may be another habitable World in the Moon: with a Discourse concerning the Possibility of a Passage thither." Lond. 1638, 8vo. This was followed by "A Discourse concerning a New Planet; tending to prove that it is probable our Earth is one of the Planets." Lond. 1640, 8vo. Both these works appeared without his name. He next produced "Mercury; or, the secret and swift Messenger; shewing how a man may with privacy and speed communicate his thoughts to a friend at any distance." Lond. 1641, 8vo. Another of his works bears the title of "Mathematical Magick; or, the Wonders that may be performed by Mechanical Geometry." Lond. 1648, 8vo. These four tracts were long afterwards reprinted in a collection of his Mathematical and Philosophical Works. Lond. 1708, 8vo. Lond. 1802, 2 vols. 8vo. The earliest of his theological works was his "Ecclesiastes; or, a Discourse of the Gift of Preaching, as it falls under the Rules of Art." Lond. 1646, 8vo. The ninth edition was printed in 1718. This publication was succeeded in 1649 by "A Discourse concerning the Beauty of Providence, in all the rugged passages of it;" and in 1653 by "A Discourse concerning the Gift of Prayer."

On the commencement of the civil wars he adhered to the parliament, and took the solemn league and covenant. The committee for reforming the university appointed him warden of Wadham College. On the 12th of April 1648 he was created B. D., and was next day admitted to the office, for which his learning, as well as his talents and temper, eminently qualified him. Next year he was created D. D., and about the same period married Robina, the sister of Oliver Cromwell, and the widow of Dr French, canon of Christ Church. The protector granted him a dispensation for retaining the wardenship, notwithstanding his marriage. In 1659 Richard Cromwell appointed him master of Trinity College, Cambridge, but he was ejected in the course of the following year. The Restoration did not however deprive Dr Wilkins of all hope of preferment. He soon afterwards became preacher at Gray's Inn, and rector of St Lawrence-Jewry. His next promotion was to the deanery of Ripon. It was about this period that he published the most remarkable of his works, "An Essay towards a Real Character and a Philosophical Language." Lond. 1668, fol. Of this essay a Latin version was completed by Ray, but was never published. During the same year, 1668, he was advanced to the bishopric of Chester; and his consecration sermon was preached by Dr Tillotson, who had married his step-daughter, Elizabeth French. The high preferment which he so well merited he did not long enjoy. Wilkins was the fourth bishop appointed to this see since the year 1660. His fatal disease was a suppression of urine, which was mistaken for the stone. He died at Dr Tillotson's house in Chancery-lane, London, on the 19th of November 1672, having only attained the age of fifty-eight. His funeral sermon was preached by Dr Lloyd, afterwards bishop of Worcester, who was himself a man of distinguished learning. His papers were left to the disposal of Tillotson, who prepared for the press his treatise "Of the Principles and Duties of Natural Religion, two books." Lond. 1675, 8vo. This work was very favourably received, and it reached a fifth edition in 1704. The same editor afterwards published a volume containing fifteen of the bishop's Sermons. Lond. 1682, 8vo. In the preface he vindicated the character of this excellent prelate from some of the malignant aspersions to which it had been exposed. Wilkins was a man of a liberal and generous mind, and was as much distinguished by his amiable disposition as by his intellectual endowments. But he was the brother-in-law of Oliver Cromwell, and had subscribed the covenant; and after the church again became triumphant, he was disposed to treat dissenters with a degree of Christian moderation and charity which the indomitable bigotry of too many churchmen could not but regard as truly scandalous. If the other prelates of that age had been animated with the same spirit, the church of England would not so speedily have been felt as a grievous scourge by a great proportion of its most pious and exemplary ministers. Richard Baxter would not have been subjected to persecution merely for preaching the gospel with a degree of zeal and fervour scarcely equalled in that secularized establishment from which he had found himself compelled to separate.

WILL, that faculty of the mind by which it embraces or rejects any thing offered to it. See METAPHYSICS.

WILLANMEZ'S ISLE, a small island off the north coast of New Britain, high in the centre, and low and wooded at the sides. Long. 149. 39. E. Lat. 5. 15. S.

WILLIAM *of* MALMESBURY, an historian of considerable merit in the reign of King Stephen, but of whose life few particulars are known. According to Bale and Pitts, he was surnamed Somersetus, from the county in which he was born. From his own preface to his second book "De Regibus Anglorum," it appears that he was addicted to learning from his youth; that he applied himself to the study of logic, physic, ethics, and particularly to history. He retired to the Benedictine convent at Malmesbury, became a monk, and was made precentor and librarian; a situation which much favoured his intention of writing the history of the kingdom. In this monastery he spent the remainder of his life, and died in the year 1142. He is one of our most ancient and most faithful historians. His principal work is that entitled "De Regibus Anglorum," in five books, with an appendix, which he styles "Historiæ Novellæ," in two more. It is a judicious collection of whatever he found on record relative to England, from the invasion of the Saxons to his own times.

WILLIAM *of* NEWBURY, so called from a monastery in Yorkshire, of which he was a member, wrote a history which begins at the Conquest and ends at the year 1197. His Latin style is preferred to that of Matthew Paris; and he is entitled to particular praise for his honest regard to truth in treating the fables of Geoffrey of Monmouth with the contempt they deserve, as well as for expressing his approbation of Henry II.'s design of reforming the clergy, by bringing them under the regulation of the secular power.

WILLIAM *of* WYKEHAM, bishop of Winchester, was born in the village of Wykeham in Hampshire in 1324. He was educated at Winchester school; and his patron Nicholas Uvedale, governor of Winchester castle, afterwards took him into his family, and appointed him his counsellor and secretary. He could not have made choice of a fitter person for that employment, no man in that age writing or speaking more politely than Wykeham. For this reason, Edington, bishop of Winchester, lord high treasurer of the kingdom, appointed him his secretary three years after, and also recommended him to King Edward III. who took him into his service. Being skilled in geometry and architecture, he was appointed surveyor of the royal buildings, and also chief justice in eyre. He superintended the building of Windsor Castle. He was afterwards chief secretary of state, and keeper of the privy seal, and in 1367 succeeded Edington in the see of Winchester. A little after he was appointed lord high chancellor and president of the privy council. That he might well discharge the several functions of his employments, both ecclesiastical and civil, he endeavoured on one hand to regulate his own life according to the strictest maxims, and to promote such parish priests only as were able to give due instructions to their parishioners, and at the same time led exemplary lives: on the other hand, he did all in his power to cause justice to be impartially administered. In 1371 he resigned his chancellorship. Edward returning to England, after having carried on a very successful war in France, found his exchequer in great disorder. The duke of Lancaster, one of his sons, at the head of several lords, having brought complaints against the clergy, who then enjoyed the chief places in the kingdom, the king removed them from their employments. But the laymen who were raised to them behaved so ill that the king was forced to restore the ecclesiastics. The duke of Lancaster showed strong animosity to the clergy, and set every engine at work to ruin Wykeham. He impeached him of extortion, and obliged him to appear at the King's Bench. He got such judges appointed as condemned him; and not satisfied with depriving him of all the temporalities of his bishopric, he advised Edward to banish him; but this prince rejected the proposal and afterwards restored to Wykeham all that he had been divested of. Richard II. was but eleven years old when Edward died, so that the duke of Lancaster had an easy opportunity of reviving the accusations against the bishop of Winchester; nevertheless Wykeham vindicated himself. He now founded two noble colleges, the one in Oxford, called New College, the other in Winchester. While he was exerting his utmost endeavours to improve these foundations, he was recalled to court, and in a manner forced to accept of the office of lord high chancellor in 1389. Having excellently discharged the duties of that employment for three years, he obtained leave to resign it, foreseeing the disturbances that were about to break out. Having returned to his diocese, he finished his college at Winchester, and there built so magnificent a cathedral that it almost equals that of St Paul's in London. He laid out several sums in things advantageous to the public and to the poor, notwithstanding which, in 1397 he was in great danger, for he and some others were impeached of high treason in open parliament; however he was again fully cleared. From that time till his death he kept quiet in his diocese, and there employed himself in all the duties of a good prelate. He died in 1404, in the eighty-first year of his age.

WILLIS, THOMAS, a celebrated English physician, was born at Great Bedwin, in Wiltshire, on the 27th of January 1621, and studied at Christ Church, Oxford. When that city was garrisoned for the king, he, among other scholars, bore arms for his majesty; and he devoted his leisure hours to the study of physic. The garrison of Oxford at length surrendering to the parliament, he applied himself to the practice of his profession, and soon rendered himself famous by his care and skill. He appropriated a room as an oratory for divine service according to the church of England, whither most of the loyalists in Oxford daily resorted. In 1660, he became Sedleian professor of natural philosophy, and the same year took the degree of doctor of physic. In 1664, he discovered the famous medicinal spring at Alstrop, near Brackley. He was one of the first members of the Royal Society, and soon made his name illustrious by his excellent writings. In 1666, after the fire of London, he removed to Westminster; and his practice became greater

Willoughby Cape || Wilmot.

than that of any of the physicians his contemporaries. He died at his house in St Martin's, on the 11th of November 1675, and was buried in Westminster Abbey. He was justly admired for his deep insight into natural and experimental philosophy, anatomy, and chemistry, for his successful practice, and for the elegance and purity of his Latin style. He wrote in English "A plain and easy Method for preserving those that are well from the Infection of the Plague, and for curing such as are infected." All his Latin works were printed in two vols. 4to, at Geneva in 1676, and at Amsterdam in 1682. His grandson, Browne Willis, LL.D., was the author of several antiquarian works.

WILLOUGHBY Cape, the eastern point of Kangarou island, on the south coast of New Holland. Long. 138. 13. E. Lat. 35. 48. S.

WILLUGHBY, Francis, a celebrated natural historian, was the only son of Sir Francis Willughby, and was born in 1635. He was fond of study from his childhood, and held idleness in abhorrence; being so great an economist with regard to his time, as not willingly to lose or misapply the least part of it; by which means he attained great skill in all branches of learning, and particularly in the mathematics. But to the history of animals, which was in a great measure neglected by his countrymen, he particularly applied himself; and for this purpose carefully read over what had been written on that subject by others. He prosecuted his studies in Trinity College, Cambridge, where he took the degree of A.B. in 1656, and of A.M. in 1659. In the following year we find him residing at Oxford for the benefit of the public library. He then travelled in search of natural knowledge, several times over his native country, and afterwards into France, Spain, Italy, Germany, and the Low Countries, attended by his ingenious friend John Ray. It is remarkable that, notwithstanding the advantages of birth, fortune, and parts, he was as humble as any man of the meanest fortune; was sober, temperate, and chaste; scrupulously just; so true to his word and promise that a man might venture his estate and life upon it; so faithful and constant to his friend as never to desert him when fortune frowned upon him; and remarkably pious, patient, and submissive to the divine will. This is the character given of him by Mr Ray, whose veracity none will doubt. This ingenious and learned gentleman died on the 3d of July 1672, at the age of thirty-seven, having impaired his health by his application. He wrote, 1. Ornithologiæ libri tres, 1676, fol. It was afterwards translated into English, with an appendix, by Mr Ray. 2. Historiæ Piscium libri quatuor, 1686, fol. 3. Letters of Francis Willughby, Esq., added to Philosophical Letters between the learned Mr Ray and several of his correspondents, and published by Dr Derham. 4. Several ingenious papers in the Philosophical Transactions.

WILMOT, John, earl of Rochester, a great wit in the reign of Charles II., the son of Henry earl of Rochester, was born on the 10th of April 1647, at Ditchley in Oxfordshire. He was instructed in classical learning at the free-school at Burford, where he obtained a quick relish of the beauties of the Latin tongue, and afterwards became well versed in the authors of the Augustan age. In 1659, he was admitted a nobleman of Wadham College, Oxford, where he was created A.M. He afterwards travelled through France and Italy, and at his return was made one of the gentlemen of the bedchamber to the king, and comptroller of Woodstock Park. In 1665, he went to sea, and was in the Revenge, commanded by Sir Thomas Tiddiman, when an attack was made on the port of Bergen in Norway. During the whole action he shewed the greatest resolution, and gained a high reputation for courage, which he supported in a second expedition, but afterwards lost it in a private adventure with Lord Mulgrave.

Before the earl of Rochester travelled, he had indulged in the most disorderly and intemperate way of living: at his return however he seemed to have got the better of it entirely. But falling into the company of the courtiers, who continually practised these excesses, he became so sunk in debauchery that he was for five years together so addicted to drinking that during all that time he was never cool enough to be master of himself. His violent love of pleasure, and his disposition to extravagant mirth, carried him to great excesses. The first involved him in sensuality, and the other led him into many adventures and ridiculous frolics. Once disguising himself so that he could not be known by his nearest friends, he set up in Tower-street for an Italian mountebank, and there dispersed his nostrums for some weeks. He often disguised himself as a porter, or as a beggar, sometimes to follow a mean amour; at other times he would go about merely for diversion in odd shapes, and acted his part so naturally that he could not be known even by his friends. In short, by his constant excesses, he entirely wore out an excellent constitution before he was thirty years of age. In October 1679, when recovering from a violent disease which ended in a consumption, he was visited by Dr Burnet, upon an intimation that such a visit would be agreeable to him. Burnet published their conferences in "Some Passages of the Life and Death of John Earl of Rochester;" from which it appears, that though he had lived the life of a libertine and atheist, he died the death of a penitent Christian. His death happened on the 26th of July 1680. His Poems have been several times printed; but when once he obtained the character of a lewd and obscene writer, every thing in that strain was ascribed to him; and thus many pieces not of his writing have crept into the later editions of his works. The earl of Oxford observes, that he was "a man whom the Muses were fond to inspire and ashamed to avow, and who practised without the least reserve that secret which can make verses more read for their defects than their merits. Lord Rochester's poems have much more obscenity than wit, more wit than poetry, and more poetry than politeness." Besides three daughters, the earl left an only son, Charles, who died in 1681, and thus the title became extinct.

WILNA, a government of the division called West Russia, of the Russian empire in Europe. It was formerly a portion of Lithuania, till the first division of Poland. In its present state, it extends in north latitude from 53° 32′ to 56° 24′, and in east longitude from 20° 54′ to 26° 33′. It is bounded on the north by Courland, on the north-east by Witebsk, on the east by Minsk, on the south by Grodno, on the south-west by the kingdom of Poland, on the west by Prussia, and on the north-west by the Baltic Sea. It comprehends 23,782 square miles, divided into thirteen circles, in which are eleven large cities, 156 smaller cities or market-towns, and 1536 villages, with 1,357,400 inhabitants. These being of Polish origin, for the most part adhere to the Romish faith; but there are a few Protestant churches both of the Lutheran and Calvinist confession. Jews are numerous, and constitute the greater part of the middle classes in all the cities and towns. They are estimated to form one seventh part of the whole population.

The face of the country is generally level, with but few undulations, none of the hills rising to the height of 300 feet above the level of the sea. The lower portions are for the most part swamps and morasses, and the higher portions chiefly covered with forests. The Baltic Sea has no ports within this government, and the sand-banks on the shore nearly render it inaccessible to ships. The river Duna touches one part, by which there is a communication with the sea, as well as by the Niemen. These two rivers receive the waters of the several small streams with which the province abounds. All these rivers have a slow course, and some of them in their progress form extensive morasses, especially on the east and south-east part of the province. In some cases they form lakes, such as the lake of Norosctz near the city of Wilna, and those of Drissewatty and of Bislau. The climate is not the mildest; the winters, though short, are severely cold, the spring and autumn moist and foggy, and even the summer, though warm, is by no means unclouded. It is however tolerably healthy, with no peculiar diseases, unless the Plica Polonica can be called peculiar, a complaint to be found in all parts of Poland, though everywhere now diminishing in frequency of occurrence.

The chief occupation is agriculture, and from it the inhabitants obtain rather more grain than they consume, and increase the quantity yearly by clearing the woods and converting them into arable land. The chief corn is rye, the next in quantity are wheat and barley, besides which oats, buck-wheat, and pulse are grown. Hemp and flax succeed well, and hops are cultivated sufficient for the breweries. The implements of agriculture are of the rudest kind. Manure is but little applied, but when the land becomes exhausted it is suffered to rest for a few years, and new land is broken up. The horses are a small and weak race, and the horned cattle, the goats, the sheep, and the swine are equally bad. The forests supply much timber for commerce, and yield pitch, tar and charcoal, and the furs of wolves, bears, martens, and other wild animals. There are no mines, or at least there is none worked, but there are valuable quarries, yielding granite, limestone, agates, flints, chalcedony, and some marble.

The manufactures are almost exclusively of the domestic kind; but the distilleries are numerous and on a large scale, and some of the spirits which they yield is smuggled over the Prussian frontier. The commerce is merely the export of a small portion of the product of the soil, and the import of a few foreign luxuries.

The capital is the city of Wilna, in the circle of its name. It stands on the river Wilia, where that stream falls into the Wileija. It is surrounded with walls, is the seat of the governor, of a catholic bishop, and of the Lutheran consistory and superintendent. It has also a university, which has the power of granting degrees in the four faculties of divinity, law, philosophy, and medicine, but, since the late insurrection, has been restricted to the last of these branches. It was before that period frequented by 400 students. Wilna is built in the ancient fashion, with narrow and crooked streets; but has still some magnificent palaces of the noble families of the province, who usually passed the winters there. It contains thirty-five Catholic churches, including an old cathedral, and the palace chapel, a most expensive building, and highly admired for one altar in it, dedicated to St Kasimir. It has also three churches for the Greeks, and one each for Lutherans and Calvinists, besides a mosque and Jews' synagogue. It contained, before the calamitous events of 831 and 1832, nearly 30,000 inhabitants. A very large proportion of them were and still are Jews. The trade and manufactures are inconsiderable, although the river Wileija is navigable to the Baltic Sea. It is 624 miles from St Petersburg. Long. 25. 11. 22. E. Lat. 54. 41. 2. N.

WILSON, ALEXANDER, the American ornithologist, was born at Paisley, in Scotland, on the 6th of July 1766. His father was a hand-loom weaver, and he himself followed the same trade. His education was more liberal than that of many in similar circumstances. Some poems which he published, especially those written in the Scottish dialect, possess great merit. In 1794 he emigrated to the United States, where, after working for some time as a weaver, he betook himself to the not less laborious but more refined employment of schoolmaster. For a series of years his time was occupied in that country with various studies, such as mathematics, the German language, music, drawing, and, above all, natural history. At length he resolved to devote himself entirely to ornithology, and, at whatever hazard, to form a collection of all the birds of the United States. For this he was eminently qualified. In the words of his American biographer, "he was not only an enthusiastic admirer of the works of creation, but he was consistent in research, and permitted no dangers or fatigues to abate his ardour or relax his exertions. He inured himself to hardships by frequent and laborious exercise, and was never more happy than when employed in some enterprise which promised, from its difficulties, the novelties of discovery. Whatever was obtained with ease appeared to him comparatively uninteresting: the acquisitions of labour alone seemed worthy of his ambition. He was no closet philosopher; he was indebted for his ideas, not to books, but to nature.... His powers of observation were acute, and his judgment seldom erred. That his industry was great, his work will ever testify; and our astonishment may well be excited that so much should have been performed in so short a time. A single individual, without patron, fortune, or recompense, accomplished, in the short space of seven years, as much as the combined body of European naturalists have taken a century to achieve. The collection and discovery of these birds were the fruits of many months of unwearied research amongst forests, swamps, and morasses, exposed to all the dangers, privations, and fatigues incident to such an undertaking. What but a remarkable passion for the pursuit, joined with an ardent desire of fame, could have supported a solitary individual in labours of body and mind, compared to which the bustling avocations of common life are mere holiday activity or recreation?" With regard to the literary merit of his "American Ornithology," passages occur in the prefaces and descriptions, which, for elegance of language, graceful ease, and graphic power, can scarcely be surpassed. In America he composed various poetical pieces. The longest of these, "The Foresters," a narrative in verse of a pedestrian journey performed by himself and two friends to the Falls of Niagara, is decidedly superior to any of a descriptive kind which he had written in Scotland, manifesting great improvement both in his taste and his power of composition. In personal appearance Wilson was tall, handsome, and vigorous; but adapted as his frame was for a life of activity, it gradually gave way under the accumulated and harassing toils to which he was subjected, and he died of dysentery at Philadelphia on the 23d of August 1813, in the forty-eighth year of his age, when the publication of his great work, which appeared in volumes, was nearly completed. Strong good sense, high moral worth, and a lofty spirit of independence, were the characteristic features of his mind. With the feelings of a poet, he had few of the defects that often cling to the poetic character.

WILSON, *Florence*, better known by his classical appellation of *Florentius Volusenus*, was born about the year 1500. He is supposed to have been born on the banks of the river Lossie, near Elgin, and to have received a part of his education in the university of Aberdeen. He afterwards prosecuted his studies at Paris, and was there employed as tutor to a son of Cardinal Wolsey's brother. Such an appointment might have led to much higher honour and emolument; but the death of the cardinal, which took place in 1530, compelled him to search for new employment. Another cardinal, Jean de Lorraine, encouraged him in the pursuit of learning, by assigning to him an annual pension, of which however the amount was probably small, nor does it appear to have been punctually paid. He likewise obtained the favour of Jean du Bellay, bishop of Paris; and in the year 1534, when that prelate was employed on an embassy to Rome, Wilson was included in his train, and had proceeded as far as Avignon, when he was detained by a malady which compelled him to relinquish his engagement. In addition to his bodily ailments, he had now to complain of the exhausted state of his purse; and thus he was again left to seek a new path of preferment. He appears to have been personally known to Cromwell, then secretary of state, as well as to Gardiner bishop of Winchester, Fisher bishop of Rochester, and Fox bishop of Hereford. On reaching Avignon, he was informed that the bishop of the diocese was anxious to find some person properly qualified to teach the public school of Carpentras. This prelate was the celebrated Cardinal Sadoleto, who was himself distinguished for his Latinity. Wilson lost no time in proceeding to the episcopal residence, where he experienced a very gracious reception. The cardinal, as we learn from one of his letters, was impressed with a most favourable opinion of his character and attainments. His nice ear was gratified with Wilson's classical Latinity; nor was he a little surprised on learning that his visitor was a native of a country so wild and remote as Scotland. He was speedily appointed master of the school, with an annual salary of seventy crowns, which at that period was no inconsiderable sum. At Carpentras he appears to have fixed his residence in the month of November 1535. To the vocation of teaching grammar he would evidently have preferred that of teaching philosophy. He did not abandon his philosophical studies, nor did he neglect the study of theology. His earliest publication was a theological tract, printed at Lyon in 1539. He next published the elegant work which has chiefly recommended him to the notice of posterity: "De Animi Tranquillitate Dialogus, Florentio Voluseno autore." Lugduni, 1543, 4to. Wilson probably continued to reside at Carpentras till the year 1546, when he had formed the resolution of returning to his native country. He seems to have cherished no antipathy towards the cause of reformation. The increasing defection from the Romish church he imputes, in terms sufficiently plain, to the pride, luxury, and negligence of the prelates; and three of the Italian reformers, Martyr, Ochino, and Lacisio, he mentions, not merely without censure, but even with undissembled approbation. Having proceeded on his journey as far as Vienne in Dauphiny, he was there arrested by the stroke of death, before the termination of the year 1546.

Wilson, *Thomas*, bishop of Sodor and Man, was born in 1663, at Burton, in Cheshire. He received the rudiments of his education at the county town, and from thence was removed to the university of Dublin. His allowance at the university was L.20 a year; a sum, small as it may now appear, which was in those days sufficient for a sober youth in so cheap a country as Ireland. His first intention was to apply himself to the study of physic; but from this he was diverted by Archdeacon Hewetson, by whose advice he dedicated himself to the church. He continued at college till the year 1686, when, on the 29th of June, he was ordained deacon by the bishop of Kildare.

The exact time of his leaving Dublin is not known, but, on account of the political and religious disputes of those days, it was sooner than he intended. On the 10th of December in the same year he was licensed to the curacy of New Church in Winwick, of which Dr Sherlock, his maternal uncle, was rector. His stipend was no more than L.30 a year; but being an excellent economist, and having the advantage of living with his uncle, this small sum was not only sufficient to supply his own wants, but it enabled him to supply the wants of others; and for this purpose he set apart one tenth of his income. In 1692 he was appointed domestic chaplain to William earl of Derby, and tutor to his son James Lord Strange, with a salary of L.30 a year. He was soon after elected master of the alms-house at Latham, which brought him L.20 a year more. Having now an income far beyond his expectations or his wishes, except as it increased his ability to do good, he set apart one fifth of it for pious uses, and particularly for the poor. In short, as his income increased he increased the portion of it which was allotted to the purposes of charity. At first he set apart a tenth, then a fifth, afterwards a third, and lastly, when he became a bishop, he dedicated the full half of his revenues to pious and charitable uses.

He had not been long in the family of Lord Derby before he was offered the valuable living of Buddesworth in Yorkshire, which he refused to accept, as being inconsistent with the resolves of his conscience against non-residence, the earl choosing still to retain him as chaplain, and tutor to his son. In 1697 he was promoted, not without some degree of compulsion on the part of his patron, to the bishopric of Man, a preferment which he held fifty-eight years. In 1698 he married Mary, daughter of Thomas Patten, Esq. of Warrington. By this lady, who survived her marriage above six years, he had four children, none of whom survived him except the late Dr. Wilson, prebendary of Westminster.

So great was the bishop's attachment to his flock, that no temptation could seduce him from their service. He more than once refused the offer of an English bishopric. There is an anecdote of Bishop Wilson and Cardinal Fleury, which reflects great credit on both. The cardinal wanted much to see him, and sent over on purpose to inquire after his health, his age, and the date of his consecration, as they were the two oldest bishops, and he believed the poorest, in Europe; at the same time inviting him to France. The bishop sent the cardinal an answer which gave him so high an opinion of him that the cardinal obtained an order that no French privateer should ravage the Isle of Man. This good prelate lived till the year 1755, dying at the advanced age of ninety-three. His Works were collected by his son in 1780, 2 vols. 4to. Another edition was published in 2 vols. fol. by the Rev. Clement Cruttwell, who likewise published an edition of the Bible in 3 vols. 4to, with notes by Bishop Wilson.

Wilson's *Promontory*, a remarkable projecting headland of granite, the southernmost point of the island of New Holland, about twenty miles in length, and from five to fourteen in breadth. Long. 146. 24. E. Lat. 39. 11½. S.

WILTON, a market and borough town of the county of Wilts, three miles from Salisbury and eighty-three from London. It stands on the river Willy, in the hundred of Branch and Dole, and returns one member to the House of Commons. It has a market on Wednesday. This place has given its name to a description of carpets first made here, and the manufactory is still extensively carried on, as well as that of some woollen cloths. Adjoining to the town is the magnificent seat and park of the earl of Pembroke. It was the residence of Sir Philip Sidney, where he composed his Arcadia. The population amounted in 1821 to 2058, and in 1831 to 1997. Several neighbouring villages have been added to the borough to form an adequate constituency.

WILTSHIRE, an inland county of England, in the western judicial circuit. It is bounded on the north-west and west by Gloucestershire, on the west by Somersetshire, on the south by Dorset and Hants, and on the east and north-east by the latter county and Berkshire. The length is about fifty miles, and the breadth about thirty-four. It is of an elliptical form, with very irregular indentations on the borders. The area is 1379 square miles, or 882,560 statute acres. The county is divided into twenty-nine hundreds, comprising one city, twenty-three market-towns, and 295 parishes. The whole of the county is in the diocese of Salisbury, and is ecclesiastically divided into two archdeaconries, which are subdivided into ten deaneries.

The population of this county amounted in 1801 to

185,107, in 1811 to 193,828, in 1821 to 222,157, and in 1831 to 240,200, thus shewing a slower progressive increase of the inhabitants than has taken place in any other of the English counties. At the last census the males were 117,622, and the females 122,534. The number of dwelling-houses was 46,281, inhabited by 51,659 families, of whom 25,045 were chiefly employed in agriculture, 15,627 were chiefly employed in trade, manufactures, and handicraft, and 10,987 were not comprised in either of the two preceding classes. At the period in question the number of males twenty years of age was 58,439; the occupiers of land employing labourers were 3387; the occupiers of land not employing labourers, 1239; the labourers employed in agriculture, 24,708; the males employed in manufactures, and in making manufacturing machinery, 3497; male servants twenty years of age, 1161; male servants under twenty years of age, 396; female servants, 7623; employed in retail trade, or in handicraft as masters or workmen, 13,080; bankers, professional and other educated men, 1792; labourers employed in labour not agricultural, 4828; other males twenty years of age, except servants, 4338.

The southern division of Wiltshire is chiefly that extensive tract of unwooded land usually denominated Salisbury Plain. It is an unenclosed country, and has an appearance of desolateness; but bottoms are frequent, and having generally streams of water running through them, the houses and villages are for the most part erected in them, and the district is much more populous than a traveller passing over the plain would suspect. The land, though chiefly used for feeding sheep, is, when brought under the plough, highly productive in turnips, barley, and wheat. There is a tract of rich land between Salisbury Plain and Marlborough Downs; and to the north of these downs the country is well enclosed, and abounds in rich pasture, on which are fed the cows that produce the excellent cheese known by the name of North Wiltshire. The peculiar breed of sheep of this county, which are universally called by its name, are all horned, afford heavy fleeces of moderately fine wool, and are very numerous; on Salisbury Plain they are said to be more than 500,000. The produce of wheat and other grain is estimated to be less per acre than the general average of the contiguous counties. There were anciently several extensive forests in this county; but, although the districts still retain the name either of *Forest* or *Chace*, they are, with the exception of Savernake or Marlborough Forest, and Cranbourne Chace, almost wholly either in pasture or under the plough.

Wiltshire being an elevated district, many rivers have their sources in it, or water the lands of it soon after their rise. The most important of these are the Thames, the Lower Avon, and the Kennet, all of which are navigable. Besides these, are the tributary streams, the Upper Avon, the Willey, the Nadder, the Bourne, the Stour, and the Brue. The canals which pass from or through this county are the Thames and Severn, connecting those two rivers with each other; the Kennet and Avon, which also unites those rivers. Both of these canals have been most expensive, and hitherto unproductive undertakings, designed to facilitate the intercourse between London and Bristol. The Wilts and Berks Canal, designed to connect the Severn with the Thames, has been a particularly unfortunate concern. The Salisbury and Southampton Canal has been found of some benefit, by supplying the former place with coals, but has been little productive to the proprietors.

This county has long been one of the chief districts for the manufacture of fine cloths. That branch of industry is now however confined to the western part of it. The populous towns of Bradford, Trowbridge, Devizes, Warminster, Chippenham, Westbury, Melksham, Calne, and the villages surrounding them, are chiefly maintained by making cloths and cassimeres of fine quality, the wool for which used to be imported from Spain to Bristol; but of late years the fine wools of Saxony have in a great measure supplanted those of Spain in this country. The fine woollen trade still employs more than 1000 males above twenty years of age at Trowbridge, about 600 at Bradford, 200 at Westbury, and some at Melksham, Chippenham, and Heytesbury. Some fine cutlery ware and steel work is made at Salisbury, but those fabrics are much reduced by their rivals at Sheffield and Birmingham. Wilton, which gave its name to a description of carpets, has still some remains of its former trade.

Few counties present so many objects of antiquarian research as Wiltshire. Among those of British origin are the Wansdike, a fortification of earth traversing the whole county; the druidical masses of stone at Stonehenge and Avebury; the numerous *barrows*, or *tumuli*, which are to be seen on a great number of spots on the downs; and the earthen ramparts supposed to have formerly enclosed the towns of the ancient Britons. Among the Roman antiquities are many of the roads constructed by that people, their fortified encampments, and the ruins of several of their castles, especially those of Marlborough, Devizes, Malmesbury, and Old Sarum. The monastic remains, especially at Malmesbury, present very interesting subjects of study to the antiquary. Besides these vestiges of antiquity, tesselated pavements, coins, urns, fragments of sculpture, daggers, shields, and ornaments of British, Roman, Saxon, and Norman fashion, have been discovered. The cathedral of Salisbury, though not of such an age as to be classed among antiquities, is an object of great admiration on account of the elegant design and scientific execution of the structure. The beautiful spire is much admired for its height and its proportions, and, though in a valley, may be seen at a great distance rising above the surrounding hills. It is said to be the loftiest in England, rising from the floor of the church to the height of 400 feet.

The peers deriving their titles from places in this county are the duke of Marlborough, the marquises of Lansdowne and of Salisbury, Viscount Bolingbroke, and Barons Arundel and Methuen. No county has undergone so great changes by the parliamentary reform bill as Wiltshire. By that law the county is divided for election purposes into north and south. The elections for the northern division are held at Devizes; and the other polling places are Melksham, Malmesbury, and Swindon. The elections for the southern are at Salisbury; and the other polling places are Warminster, East Everley, and Hindon. Each of these divisions returns two members. By the reform bill the following boroughs, each of which returned two members, have been disfranchised; viz. Old Sarum, Ludgershall, Hindon, Great Bedwin, Heytesbury, Wooton-Basset, and Downton; and the following towns, which chose two each, have now but one; viz. Westbury, Wilton, Malmesbury, and Calne. No new boroughs were created in the county, but the following places retain their ancient privileges of electing two members each; viz. Salisbury, Chippenham, Cricklade, Devizes, and Marlborough. The towns and the population exceeding 4000 persons are, Trowbridge, 10,863; Bradford, 10,102; Salisbury, 9876; Westbury, 7324; Warminster, 6115; Melksham, 5866; Calne, 4795; Chippenham, 4333.

Among a great number of seats belonging to noblemen and gentlemen, the most remarkable are Longleat, the marquis of Bath; Bowood, marquis of Lansdowne; Tottenham Park, Lord Aylesbury; Wardour Castle, Lord Arundel; Fonthill Abbey, Mr Morrison; Wilton, earl of Pembroke; Stourhead, Sir R. C. Hoare, Longford Castle, earl of Radnor; New Park, Thomas Estcourt, Esq.; Dinton House, William Wyndham, Esq.; Corsham House, Lord Methuen; Wilbury House, Sir C. W. Malet; Charlton Park, earl of

Wimbledon || Winchester.

Suffolk; Stoke Park, Joshua Smith, Esq.; Bradley, duke of Somerset; and Ramsbury, Sir Francis Burdett.[1]

WIMBLEDON, an extensive parish of the county of Surrey, in the hundred of Brixton, seven miles from London. The village consists of one main street on the great road to Portsmouth, but is most remarkable for the number and elegance of the residences around its common, and in other parts of the parish. The most striking of these is the seat of Earl Spencer, and the park which surrounds it, originally built by Lord Burleigh in 1588, and afterwards rebuilt by Sarah duchess of Marlborough. Many others are deserving of attention. The population of the parish amounted in 1821 to 2195, and in 1831 to 2195.

WIMBORN-MINSTER, a market-town of the county of Dorset, in the hundred of Badbury and division of Shaftesbury, 100 miles from London and seven from Poole. It is finely situated between the rivers Stour and Allen, over each of which are bridges. Its name is derived from the minster, a Gothic-Norman structure, which now serves as the parish church. It has a lofty tower in the middle, and another at the west end, and in the choir are fourteen stalls. The town has a good market-place, well attended on Friday, an endowed grammar-school, and several charitable foundations. The population amounted in 1821 to 3563, and in 1831 to 4009; but in this estimate are included the inhabitants of three tythings within the parish.

WINCANTON, a market-town of the county of Somerset, in the hundred of Ferres-Norton, 108 miles from London. It has a market on Wednesday. What little trade there is, consists in making tickings, dowlas, and other coarse linen goods. The population amounted in 1821 to 2143, and in 1831 to 2123.

WINCHCOMBE, a market-town of the county of Gloucester, in the hundred of Kiftsgate, ninety-six miles from London and six from Cheltenham. It is situated in the Cotswold Hills. It is a place of great antiquity, and was once deemed a county of itself, having exempt jurisdiction. The church is deserving of notice, being a fine Gothic structure, and the burying-place of some of the ancient kings of Mercia, one of whom, Kenulph, founded a Benedictine monastery in the sixth century. It is still a borough, governed by two bailifs. Till the reign of Charles II., this place was the chief seat of the cultivation of tobacco in England. There is now a good market on Saturday. The population amounted in 1821 to 2240, and in 1831 to 2514.

WINCHELSEA, a town and parish of the county of Sussex, in the hundred of Guestling and rape of Hastings, sixty-seven miles from London. It stands on a rising ground, overlooking marshes which extend to the sea. The ancient town of this name was once a large city, and contained a harbour and eighteen parish churches, nearly the whole of which have been swallowed up by tempests, and by the receding of the land. The present town, which is distant from the sea a mile and a half, is built upon an eminence, and was erected in the reign of Edward I. In various parts of the town are spacious stone-vaults, and extensive ruins. An attempt was made to introduce the manufacture of cambrics into this town, but it was attended with no success. The small market is on Saturday. The population amounted in 1821 to 817, and in 1831 to 772.

WINCHELSEA *Island*, in the Gulf of Carpentaria, New Holland, near the coast of Groote Eylandt, with which it forms a bay, called by Captain Flinders North-west Bay. It is about five or six miles long. There is another island of this name in the Pacific Ocean, thirty miles south-east of Sir Charles Hardy's Island.

WINCHESTER, a city in Hampshire, of which it is the capital, sixty-two miles from London, and eleven from Southampton. It is built on the side of a hill, and on the level below it, which extends to the banks of the river Itchin. It is a remarkably clean place; and though many of the houses are in an antique style, it is well built, and the streets, though some are narrow, are well paved and well lighted. The country around it is fertile, yielding supplies, to the two weekly markets on Wednesday and Saturday, of the best kinds of meat, vegetables, fish, and all other requisites for subsistence. With the sea it has a communication by a canal, by which coals and other heavy commodities are furnished at moderate rates. From these circumstances, the city is inhabited by many respectable families in moderate circumstances, as well as by professional persons drawn to it as the county-town, and on account of the cathedral, the college, and other public institutions.

This city is one of the most ancient in England. It was known in the time of the Romans. During the contests of the Britons and the Saxons it became the capital of the West Saxons, and, under the reign of Egbert, the capital of the whole kingdom; and it was not till the reign of William the Conqueror that London began to rival it, though not then the royal residence. In the reign of Edward I., who preferred London for his abode, Winchester felt the effects of the royal abandonment, in the loss of the numerous attendants on the king, and of those who had repaired to the supreme courts of law. Edward III. erected this city into the staple or mart for wool, which gave to it some animation; but the plague, which raged in the city and neighbourhood, caused the removal of the trade to Calais, then an English fortress, about the year 1360. The dissolution of many religious houses in the reign of Henry VIII. inflicted great calamities on the city, and reduced its population, its wealth, and its extent. During the civil war of the reign of Charles I., it was seized by the parliament forces under Waller, and to this day it is related that he converted the cathedral into horse-barracks, and caused much injury to many other sacred edifices. In 1643, the king's forces seized upon it, and converted Winchester into a garrison town, which, after the battle of Naseby, and a short siege, surrendered to the forces of Cromwell. The fortifications and castle were then destroyed, as well as the bishop's palace at Wolversey, and several churches and other public buildings, few of which were replaced after the restoration. The last historical event relating to the place is the plague of 1665, which swept away a great portion of the inhabitants. Among the objects deserving attention, one of the most beneficial in the present day is the college, founded by William of Wykeham, then the bishop, between the years 1387 and 1393. It was built on the site of an ancient grammar-school, certainly existing in 1136, and probably at an earlier period. The building consists of two large courts, highly ornamented with ancient sculpture, and a chapel, the ceiling of the vestibule of which is much admired, while the interior has a fine effect, from the bold and lofty vaulting being richly adorned with tracery, and a variety of sculptures, representing kings, prelates, and saints. Near to the college are the cloisters, 132 feet square, a detached building for those pupils who are not on the foundation, and a library. The establishment of the college consists of a warden, ten fellows, seventy scholars, three chaplains, and masters. This foundation is connected with New College, Oxford, where the Winchester scholars become fellows. It has long been a flourishing institution, and here some of the most distinguished scholars have received their early education.

The cathedral of Winchester is one of the most interesting buildings in the kingdom, considering its antiquity, the historical events of which it has been the theatre, and the character of the persons whose mortal remains have been deposited within its walls. It is also curious as exhibiting instructive specimens of the Saxon, Norman, and English styles of architecture, and of the gradual steps from one to another of them. The various parts of this building, the periods of their erection, and the most minute particulars of every portion, have been so elaborately and accurately detailed by the pen of Dr Milner, a Catholic bishop, and by others, that we must refer to their works, more especially as our limits will not enable us to do justice to the admirable impressions made on surveying the whole. On the authority of Milner, we give the following as the dimensions of this magnificent building. The whole length of the cathedral is 545 feet, length of the nave from the west porch to the iron doors at the entrance of the choir 351 feet, length of the choir 136 feet, breadth of the cathedral, eight-seven feet, and of the choir forty feet, length of the transept 186 feet, and height of the tower 150 feet. Since the work of Milner was published, the impression made on first entering the building has been greatly heightened by the removal of the screen erected in the time of Bishop Fox. It is said that formerly there were in Winchester between eighty and ninety churches. At present there are only eleven remaining, most of which are very ancient, and all deserving of inspection by the lovers of antiquities.

---

[1] See the Ancient History of South Wiltshire, by Sir Richard Colt Hoare, Bart.: Aubrey's Introduction to the Survey and Natural History of North Wiltshire; the Beauties of Wiltshire displayed in Statistical, Historical, and Descriptive Sketches, by John Britton; Davis's View of the Agriculture of the County of Wilts.

The ancient castle has been converted into a county-hall in which is shewn the celebrated round table attributed to King Arthur. In the town-hall, built on an ancient foundation, is preserved the bushel measure given by king Edgar, which still bears the name of this city. The market-cross is a striking building, and a specimen of the style of Henry VI. Overlooking the city is the King-House, an unfinished building, erected by Charles II. It has never been inhabited except by French prisoners in time of war. Within the confines of the city is the monastery of St Cross, now converted into a respectable kind of alms-house; and there are many other charitable institutions. The city, divided into three wards, is governed by a mayor, six aldermen, and eighteen councillors. It returns two members to the House of Commons. The population, including the extra parochial, amounted in 1821 to 7741, and in 1831 to 9212.

WIND is a sensible agitation of the atmosphere, occasioned by a quantity of air flowing from one place to another. See METEOROLOGY.

WIND-GAGE. See PHYSICAL GEOGRAPHY, vol. xvii. p. 338-9.

WINDLASS, a machine used for raising huge weights, as guns, stones, anchors, &c. It is very simple, consisting only of an axis or roller, supported horizontally at the two ends by two pieces of wood and a pulley: the two pieces of wood meet at top, being placed diagonally so as to prop each other; the axis or roller goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two staves or handspikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abaft the fore-mast. It is made of a piece of timber six or eight feet square, in form of an axletree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if, in heaving the windlass about, any of the handspikes should happen to break, the windlass would pall of itself.

WINDOW, an aperture or open place in the wall of a house to let in the light. Before the use of glass became general, which was not till towards the end of the 12th century, the windows in Britain seem generally to have been composed of paper. Properly prepared with oil, this forms no contemptible defence against the intrusions of the weather, and makes no incompetent opening for the admission of the light. It is still used by our architects for the temporary windows of unfinished houses, and not unfrequently for the regular ones of our workshops. But some of the principal buildings we may reasonably suppose to have been windowed in a superior manner. They could however be furnished merely with lattices of wood or sheets of linen, as these two remained the only furniture of our cathedrals nearly to the eighth century; and the lattices continued in some of the meaner towns of Lancashire to the 18th, and in many districts of Wales, and many of the adjoining parts of England, are in use even to the present moment. These seem all to have been fixed in frames that were called *capsamenta*, or casements.

WINDSOR, a borough and market town of Berkshire, twenty-two miles from London, on the banks of the Thames. Old and New Windsor, the castle, and the hamlets of Clewer and Dedworth, are included in the parish. Windsor stands on the side and top of a hill sloping to the river. It is divided into two wards, and is governed by a mayor, six aldermen, and eighteen councillors, and it returns two members to the House of Commons. The parish church is a spacious building in the High-street; and near it is the town-hall, a neat structure supported by columns and arches of Portland stone. There are also many good houses belonging to individuals. The population, including that of the castle, amounted in 1821 to 5698, and in 1831 to 7103. The chief object of admiration is the castle, a royal residence, with its park, and adjoining to it a tract of land of fifty-six miles in extent, denominated Windsor Forest. The castle or palace is a beautiful pile of building, on an eminence, which makes it visible to a large extent of the surrounding country. The terrace, overlooking the Thames, is a magnificent promenade, nearly the third of a mile in length, from which the views are richly expanded. The interior consists of two courts, surrounded with apartments for the royal family and domestics. These are magnificently furnished, and adorned with pictures, statues, and other valuable curiosities. Within the castle is St George's chapel, a most elegantly finished building, with beautifully painted glass windows; and under it are the vaults in which are deposited the remains of many of the successive monarchs of this kingdom, and of the members of their families. The recent repairs and additions have been made with great taste, and at an enormous expense.

WINDWARD, in the sea-language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward tide is the tide which runs against the wind.

WINKOOP'S ISLAND, a large island on the south coast of Java. Long. 106. 36. E. Lat. 7. 28. S. There is a bay of the same name on the south coast of Java. Long 106. 38. E. Lat. 7. 5. S.

WINE-MAKING.

Wine-Making.

The history of wines is both curious and amusing; and their topography is not less so, if we may apply this term to the several kinds, to their enumeration, and to that of the countries where they grow, and to the variations followed in their manufacture. This is a subject which would occupy a volume; and we must therefore pass it over, that we may dwell on what is of more moment, the general mode of making this important article, and the several chemical circumstances connected with it. France is the only nation which has bestowed much attention on the philosophy of wine-making, as it is that which excels all others in the variety and the goodness of its produce.

Fruits, their nature.

Vinous liquors, resembling wine, may be made from every fruit, as well as from every vegetable which contains acids united to its extractive matter. The term wine is thus applied to the produce of currants, gooseberries, and many others; while that of cider is especially reserved for the liquor to be obtained from apples. That term would be a fitter one for many of the vinous liquors in question, and we shall here restrict the term *wine* to the produce of the vine.

All fruits consist of the following principles: water, sugar, a peculiar combination of sugar and extract, called the sweet principle by the French, supertartrite of potash, malat of potash, and malic acid, superoxalate of potash, extractive matter analogous to mucilage, and vegetable gelatin, tannin, a principle of flavour, and a colouring principle. These however are not all found in any one fruit, and they also vary in their proportion in different fruits. The essential ones to the making of wine are the tartarous acid, sugar or the sweet principle, extract, and water; and those which are useful, without being indispensable, are flavour, tannin or astringency, and colour. And it is by possessing these in right proportions that the grape excels all other fruits for the purpose of making wine.

Effects of the principles of fruits.

Tartarous acid, or its combinations, are especially indispensable: and hence it is that the grape, which contains it in large quantity, produces wine; while the apple, and other fruits which contain the malic acid, produce cider. It is essential to the fermentation, as well as to the quality of the produce; and it is decomposed in the process so as to increase the quantity of alcohol, which the sugar would otherwise yield. Where malic acid is also present, the quality of the wine is bad. Sugar must be considered the fundamental element, and as that from which the alcohol is chiefly derived. Thus the most saccharine grapes produce the strongest wine. But it seldom exists in a pure state in the grape, or in any other vegetable. It appears to be most pure in the sugar-cane; but even there it is combined with the extractive matter, and also with some acid, forming the sweet principle of the French. Pure sugar does not ferment in water, it crystallizes; and whenever fermentation occurs, some other vegetable matter is present. When sugar, again, has crystallized from a solution of the sweet principle, what remains runs still more readily into fermentation. In the produce of the cane, this is molasses. It is very important to keep this distinction in view, because the fabrication of sweet wines depends materially upon it. It explains many circumstances in the process of fermentation, and some that are often overlooked. It explains, among other things, why wine ferments in a cask when it will not ferment in bottles; because the sugar derives the necessary extractive matter from the wood. The chemical nature of the extractive matter is not known, but it is supposed to contain azote, as this is the produce of fermentation. Yeast, or leaven, contains the extractive principle in great abundance, and hence its power in inducing fermentation in a solution of pure sugar. All vegetables contain it; and it is most abundant in those juices which gelatinate in boiling. It is found in the grape, and it is thus the natural leaven of wine, whether existing in a separate state, or united to sugar in the form of the sweet principle. Water is a much more essential ingredient than would at first be suspected. If over-abundant, it is difficult to prevent the produce from running to the acetous stage. Hence weak wines become sour. If deficient, it is difficult to establish the fermentation; and hence sweet wines. Thus also sweet wines are insured by drying the grapes, or evaporating their juice, both common practices in the wine countries. Colour must be looked on in the light of an ornament, and is found in the husk of the grape. So is the tannin principle, which occasions astringency in Port wine. Of the principle of flavour chemistry knows nothing; it seems often the produce of fermentation, as in Claret and Burgundy wines: in those of Frontignan and Muscat it is the natural flavour of the fruit.

On fer- mentat

When the process is complete, the wine is dry, or contains no sugar, so that sweet wines, which are compounds of wine and sugar, are the produce of an incomplete fermentation. When all the elements above described are in due proportion, the product is perfect, a dry wine; and the elements that require particularly to be balanced for this result are the extract or leaven, and the sugar. If the former is in excess, the wine tends to vinegar, unless means are used to stop the fermentation by abstracting the leaven; if in defect, the product is imperfect, a sweet wine. Hence the perfection and management of the leaven are among the most important circumstances in the manufacture. It is coagulable partially by heat; and hence also it is, as well as by evaporating the water, that boiled *must* produces sweet wine. It is also abstracted by precipitation, and by the action of sulphurous acids; whence other processes in use in wine-making.

In fermentation, the superfluous extract or leaven is separated in two forms, that of yeast and lees; and these will excite that process in fresh solutions of sugar, or renew it, or continue it, in the mixture whence it was separated; whence racking and fining. There is however one important difference between the natural or original, and this artificial or secondary leaven. The latter is soluble in hot water, and not in cold; and hence it is separated in fermentation. By restoring this separated matter to wine in the course of fabrication, the fermenting process is prolonged, or the wine rendered drier; by skimming, and fining, and racking, the process is checked; and hence the application of these practices to sweet wines. The *rolling* of wine, or returning on its lees to *feed*, is hence understood; and hence also the improvement which certain wines experience in long voyages. But the same principle and process which improves Madeira destroys Burgundy, and the reason must now be obvious. The theory of racking, fining, and sulphuring, is hence also apparent; and, of the sulphurous acid, it is a property to combine with the leaven, and form an insoluble separable compound. It is thus that it checks fermentation. Hence also it is that sweet wines do not turn sour: their leaven has been expended. Thus also we may see that the process of fermentation is not an unmanageable and a precarious one; but that the essential ingredients are in our power, and that we can modify them to the desired result. If it has been stopped prematurely, it may be renewed by fresh leaven; if in ex-ces it may be checked or suspended. And thus it is, too, tha dry wines, and fined wines, and wines in bottles, are du ble, when they would perish in the cask.

he acid was shown to be also essential to the produce of ine. Mere extract, or leaven, and sugar, produce beer, no wine. Tartarous acid cannot well be in excess in that co pound in which it exists, viz. the supertartrite of potash; be use it is a salt of difficult solution, and the superfluity is recipitated; hence the tartar of wine-casks; hence als the crystals which are seen, in cold weather, to float in adeira wine. We noticed that it was decomposed in th fermentation, and was thought to contribute to the qu tity of alcohol. The French chemists also assert that a rt of it is converted into the malic; hence the peculiar pr erties of some wines; hence also the practice of liming th vats, or of sprinkling the grapes with lime in the manufa ure of Sherry wines, whence they acquire that peculiar dr and hard taste which distinguishes them from the wines of adeira. As the tartarous salt adds to the fermenting po er of the fluid, hence we explain the facility with which th juice of green grapes runs into fermentation when compa d with ripe ones; the immature fruit containing a much la er proportion of this salt than the mature. Thus also th e wines continue to ferment longer, or to retain the po er of fermenting; and hence the vivacity of Champagne wi es, the most effervescent kinds of which are made from ha -ripened fruit.

he temperature of 54° Fahrenheit is considered the m t favourable to this process. In extreme heat it fails, as n extreme cold. Hence the difficulty of making wine in ndia and the West Indian islands. Hence also, in the te perate climates, we have it in our power to regulate fe mentation by the use of heat or of cold. Hence also it that wines which had ceased to ferment, recommence in pring; and hence one of the processes essential to the m nufactures of Champagne wines, namely, that of watching th spring fermentation, and bottling the wines in this stage.

ir is necessary to fermentation, rather than essential. T e operation does not cease in closed vessels, but is reta ded. Air is not absorbed in the vinous fermentation, al ough its oxygen is in the acetous. The wine is s nger in close vessels if the process is slower, because a p tion of the alcohol escapes from the vats; and this is n understood in our malt distilleries. That alcohol is h d in solution in the carbonic acid which is generated, a thus it appears to intoxicate more rapidly; as is well k wn in Champagne wines. Under pressure, this comp nd is united to the fluid; and being disengaged, prod es the well-known effervescence. The practice of ferm ntation is partly regulated by this consideration. The v lent stage of that process in wine-making is allowed to t e place in an open vat, the next is partially checked by a occasional bung, and in the last of all the vessel is comp tely closed. In strong still wines, the whole process may b conducted in open vessels; but in light and brisk ones, i s absolutely necessary that the last part should take p ce in closed ones. Champagne wines are managed so a o ferment even in their bottles.

he volume of the fermenting fluid has a considerable e ct on the process; a few days are sufficient to complete it when the quantity is large. When small, it is difficult t establish, and tedious in the progress, and the results are a different; wines of different qualities being thus prod ed from the very same materials. It is the same in the u mate fermentation or ripening of wines. Champagne w ld be destroyed in a large cask: porter, an extreme c e, is ripened in enormous quantities, as are many of the s nger wines. Bulk is peculiarly required for the strong a sweet wines; Champagne may be made in a gallon m sure.

he first appearance is the production of air-bubbles, terminating at length in a general ebullition. The liquor then becomes turbid, a variety of solid matters are disengaged, some falling to the bottom, and others rising to the top of the fluid. The leaven before mentioned is thus separated among other matters, while the bulk of the fluid is materially increased. It is in this stage that we have the power of regulating the extent of the fermentation, by separating the floating leaven, or allowing it to return into the liquor. Hence the process of fermenting in a full cask ejecting that substance by the bung-hole.

Phenomena of fermentation.

The disengaged gas is chiefly carbonic acid; but holding, as first remarked, some alcohol in solution. It appears by analysis that this is the produce of part of the carbon of the sugar and of its oxygen; and this is the great change which leads to the production of the alcohol. But it also contains some obscure vegetable matter in suspension; because, if passed through water, it not only converts it into vinegar, but deposits that mucilage which in vinegar is called the *mother*. It is possible, however, that this may itself be a new compound; and it is one which, in certain cases, contains azote. That substance, which exists in yeast, has also been found in the disengaged gas, partly, it is said, in the form of ammonia; and hence, possibly, a nauseous ammoniacal taste, well known in bad wines, and very remarkable in those of the Cape of Good Hope.

The generation of heat is one of the most remarkable phenomena in fermentation, and it bears a proportion to the bulk of the fluid. It is sometimes so great as to render it necessary to reduce it by art; its cause is obscure. The colour of wines is also produced during the fermentation; the red appears to be a substance analogous to resin, soluble in alcohol; and thus its production is accounted for. Hence white wines may be made from red grapes, by excluding the husks; hence also red wines are often astringent, because the tannin also lies in the husk. Thus also, in Champagne wines, the red are generally inferior, because the species of fermentation required to extract the colour dissipates part of the flavour.

The formation of alcohol is the last and the essential phenomenon; and it is now plain how this must depend on the quantity of sugar, on the goodness of the fruit, on the due apportioning of the leaven, and on the management of the process.

Thus, when all the necessary circumstances are present, the process goes on till the produce is pure wine, or a compound of alcohol, water, acid, colour, vegetable extract, and sugar. For although the two latter are said to be destroyed, there is almost always a minute portion of both remaining; the former rendered very sensible, in some wines, by the skinny matter which it deposits on the sides of the bottles. In a similar manner it happens that a portion of sugar continues attached to the wine for a long time, though it is not always sensible except to a fine taste. Thus it is perceptible in Claret, and even in Madeira, which are among the driest of our wines. It is often very sensible in Port, and when in excess is commonly the mark of a bad wine. In the first stages of the fermentation the sugar is never thoroughly decomposed. If that were the case, indeed, the process would stop, or it would proceed to vinegar. Further fermentation, that slower species which takes place in the casks, tends further to diminish it; but still a portion remains, even when it has been bottled.

It is the gradual conversion of this sugar, the chief operation that goes on in bottled wines, which is the cause of the change which these undergo. This process often requires many years for its completion: that is the case in the Clarets of Chateau Margaux, and other Bordeaux wines; and the same process indeed takes place to a greater or less degree in Madeira and the other strong wines. In these cases it is a cause of improvement, the wine becoming more perfect under this last tedious fermentation; in others however it is mischievous, and hence the destruction of many wines. Thus Champagne is destroyed, and often very quickly: thus Burgundy also is easily ruined; and thus even our Port is not a very durable wine, though the destruction is here accelerated by the intermixture of brandy used in this particular manufacture. Age, which thus meliorates one wine, destroys another, independently of that loss of flavour which occurs in some of the more delicate, though this also is the result of the slow fermentation under review. In the sweet wines the same process tends constantly to diminish that sweetness; and hence the comparatively dry qualities of ancient Malmsey and of Paxaret under the same circumstances. In this class of wines also the flavour is injured by the same process, or by age; and hence, though age may confer merit as well as honour on Malmsey and Malaga, and generally on the sweet Spanish and Greek wines, which have little flavour, by diminishing their lusciousness, it destroys or injures the highly perfumed wines of Frontignan, which can scarcely be drunk too new.

By the same considerations we can account for the benefit which Madeira wines receive in a hot climate, or in a hot cellar. The effect of the heat, and, in the case of a sea-voyage, united to the agitation, whose action was considered before, is that of accelerating the imperceptible fermentation, and thus ripening the wine sooner than would have happened in a low temperature and at rest. But it is a mistake to imagine that this is peculiar to Madeira, or that it is the only wine which can be benefited by this treatment. It is the same for all the Spanish wines, for Sherry and for Port; and it is also true of the better and safer wines of France, of those of Hermitage and the Bordelais. Claret becomes drinkable in a much shorter time in a warm than in a cold cellar; and that is equally true of many more of these wines. But that which some will bear, others will not; and thus many of the wines of France, so far from admitting a high temperature, can scarcely be preserved even in a low one. As to Port, it is a useful piece of knowledge to be aware that it may speedily be rendered aged by heat. And in this case it deposits its colour, and assumes the marks of old wine to the eye as well as to the palate. One year will thus do that for Port which might have required five or six; but the period of its entire duration is consequently shortened, as might be expected. The effect of heat is indeed such in this case as is suspected by few. In America it is a well-known practice to boil Madeira, or to heat it to the boiling temperature; and the effect is that of rendering it good and old wine, when previously harsh and new. The same practice is applicable to Port. If newly-bottled wine be exposed to the sun, it begins shortly to deposit, and improves in flavour; and even the rawest wine of this kind may, by heating it in hot water, be caused, in the course of a day, to assume the quality which it would have had after many years of keeping. It is so far from being injurious, as might be imagined, that it is a valuable secret; and, as we believe, one that is but little known to those whose interest it is to give the complexion of old wine to new, and who generally effect this purpose in a fraudulent manner, by putting it into foul and crusted bottles.

It is important, in another view, to consider the effects which follow from a portion of undecomposed sugar remaining in wine. It is supposed to be a means and a test of the security of wine; and the French chemists assert, that as long as any portion remains undecomposed, such wine cannot run into the acetous fermentation. This appears true only in a limited sense. In Hock, it would seem as if every atom of sugar had vanished, and yet the durability of that wine appears to be endless. If that is not absolutely the case in Claret and Madeira, still these are very durable wines; the most so, after Hock, at least of the dry class. None of these, when of a good quality, ever runs into the acetous fermentation. Perhaps this may depend on some peculiar balance of principles, which chemistry has not yet found the means of discovering; for, in other cases, it is certain that the chemists in question are under an error, and that the acetous fermentation will come on though sugar should still be present. This happens in many of the French wines of the lighter kinds. If, in the sweet wines from the grape, that effect does not take place, it is very certain that it happens in the wines made in this country in imitation of them from various substances. In these cases even sweet wines are found to be occasionally *pricked*, as the technical term is, or vinegar and sugar are co-existent in the fluid at the same time. Nor are even all the foreign sweet wines of the grape exempt from this disease; as must be well known to those who have an extensive knowledge of wines, or of the wine market.

There is reason to believe, that the cause of this must be sought as a circumstance which these chemists seem to have overlooked. If the balance of principles in a sweet wine has been perfect, and the process of fermentation has also been complete, and if, in addition to this, these wines have been so carefully racked and fined that no lee or leaven remains in them, they may be safe, because there is nothing left in them to re-excite a fermentation, or to bring on the acetous stage. But if that is not the case, if any impurity, any leaven in any form remain, the sweetness offers no security against the change into vinegar, or at least against the partial change which constitutes a *pricked* wine. The acetous fermentation may commence, and proceed as far as the circumstances allow; and thus vinegar and sweet wine may exist together in the fluid. The nature of the acetous fermentation is indeed very ill understood, as little as that of the vinous; and we are at present incompetent to reason much about it. It is a common opinion that it must be preceded by the vinous; yet this does not appear to be true. Certain mixtures of sugar, leaven, and water, will immediately tend to vinegar, without our being able to detect a previous vinous stage; and this seems always the case when the solution is very weak, or the water in large quantity, provided, of course, there be access of air. It is indeed unquestionable, that in the common process of making vinegar, the acetous fermentation is going on in a saccharine fluid, so that the mixed taste of vinegar and sugar is perceptible until that process is completed. Vinegar can also be produced by passing alcoholized carbonic acid through water, another obscure operation; and in the human stomach it is produced in a very few minutes, when we can scarcely imagine that any previous vinous stage can have taken place.

Management of fermentation.

When all the favourable circumstances above stated are present, the fermentation begins, and passes through its regular stages, till there is produced wine, perfect and dry if the sugar has been thoroughly and accurately proportioned to the other ingredients; sweet if it has been in excess; and acid, as in Hock, when this substance has been in undue proportion to the other ingredients. The unfavourable circumstances must be sought in the temperature, or in the quality of the fluid. The juice of the grape rarely labours under any defect but the want of sugar, arising from a bad variety of this fruit, from a bad season, or from imperfect ripening. In the latter case, however, there may be added to defect of sugar or excess of water, an excess of acid and an excess of extractive matter.

In the wine-countries, the defect of sugar is remedied by different expedients. In some, sugar or honey is added to the juice or must; in others, a portion of the juice is evaporated and added to the rest; and sometimes all the juice is boiled before it is submitted to fermentation. These seem to have been the *vina cocta* of the ancients, which, from other circumstances, we know to have been thick and sweet wines, requiring dilution. They could not have been boiled to any consistence after they had become wine, without losing all their properties; and as to wines that were to be cut by a knife, it is plain that we must have misapprehended the meaning of the term *vinum* in this case, as no wine could exist under such a form. To gain the same end, it is a practice in many countries to dry the grapes partially, by suffering them to remain on the vine; but this is chiefly resorted to for sweet wines, as in the case of Cyprus, Tokay, Lipari, and others. The other expedient for increasing the properties of sugar in the juice is by plaster of Paris or gypsum, not an uncommon ingredient; and this effect, as well as that of absorbing and destroying superfluous acid, is also partially attained by the use of lime.

The management of the fermentation, supposing the fluid to be perfect, is regulated by the intended nature of the wine. If sweet wine is desired, not only must the proportion of the water be diminished by one or other of the means above mentioned, if necessary, but the proportion of extractive matter or leaven must be reduced, to prevent it from running to the ultimate stage, and producing a dry and strong wine. In this case the yeast is separated as fast as it rises, by mechanical means; as by fermenting in full casks in such a manner that it may be continuously ejected at the bung-hole as fast as it is formed. Should the reverse be desired, or a dry wine be the manufacturer's object, the yeast is suffered to remain on the surface in the vat, that it may be continually returned into the liquor by the internal agitation; or else it is stirred, or rolled in a cask or in the vat, so as to protract the fermentation. Lastly, if the wine is to be brisk, to retain carbonic acid, as the wines of Champagne, not only must the proportion of water and leaven be increased, but the fermentation must be conducted in vessels partially closed, and these also must be fully closed before the fermentation is completed. The management of the temperature is easily deduced from the principles already laid down. A deficiency of heat is easily remedied by artificial means, by a fire, or by exposure to the sun; and this is sometimes done by heating a portion of the fluid, and then mixing it with the mass. An equal temperature in the vat is also procured by agitation; and when it is necessary carefully to maintain a mean heat, this is frequently done in the wine-countries by surrounding it with straw or other bad conductors, or by other obvious artifices.

On apparently minute attentions of this nature, far more depends than would, on a superficial view, be imagined; and the great superiority of the wines of France above those of Spain, Italy, and Greece, often depends much more on delicacies of this nature than on any difference in the quality of the grape. In wine-making, indeed, more seems often to depend on art than on nature; and it is both to the praise and advantage of the French, that, by these minute attentions, they have contrived to excel all Europe in this art. Italy, Spain, and Greece, with better climates, and every natural advantage, are thus the manufacturers of a thousand detestable wines, which, in the hands of Frenchmen, might rival the produce of that country. The recent improvements made in the Sicilian wines in new hands, are a proof of how much depends on these attentions; and those who have drunk the nauseous, putrid, acid, and disgusting common wines of Italy and Spain, where nothing is wanting but management and care, will know how to appreciate the value of these.

In conducting the fermentation, some other considerations are necessary, on which some remarks are also required. The first of these is the flavour. That evanescent and delicate property, the *bouquet*, as it is called, depends on attentions no less minute. The flavour is very apt to be dissipated by a violent or a long fermentation, or by an open one; and hence, for the finer wines, great care is required through every stage of that process. It is the same for the brisker wines; as, if this be neglected, this volatile substance, on which their peculiar property depends, may be irrecoverably dissipated. A consideration of the general divisions of the quality of wines will render these remarks more intelligible.

They may be divided into four classes; the sweet and strong; the dry and strong; the delicate and light, which are generally weak compared to the former; and the effervescent or brisk. Malmsey, Tokay, Frontignan, are examples of the first; and the second are peculiarly familiar to Britain. Hermitage holds an intermediate rank, as does Claret, between these and the third class; of which the lighter Burgundy wines, the white wines of Greece, and those of the Rhine and the Moselle, may be considered pure examples; and, of the last, Champagne is almost the only one that deserves to be named.

If therefore the intention is to make either a strong sweet wine or a strong dry one, the fermentation is commenced in an open vat. But in the former case it is not suffered to remain there long, as it is in the latter. For the driest wines, or for those which are manufactured for distillation, the fermentation is allowed to expend itself in the vat, and the wine is not tunned till it is made; the completion of the process merely, or the final solar fermentation, being reserved for the cask. In the sweet wines, on the contrary, it is soon removed from the vat to the casks, that it may be more in the operator's power to suspend the process, and thus to prevent the annihilation, or total conversion, of the saccharine matter. In the third class, again, in the highly flavoured wines, of which Burgundy may be selected as an example, the fluid is only suffered to remain a few hours in the vat; from six perhaps to twenty, that period varying according to the state of the temperature, the particular quality of the juice as to goodness or strength, and the other views of the manufacturer. This is done to prevent the dissipation of the flavour, which would be injured, if not destroyed, by an open fermentation. The same practice is followed for the wines of Champagne, though there is little flavour to preserve; the purpose being in this case to secure the power of checking the fermentation by pressure, so as to retain the wine in a low stage of this process, and thus to secure a supply of mixed or combined carbonic acid at the period of use or drinking.

Further precautions in fermentation.

There is nothing which more strongly distinguishes the bad or inferior wines of Spain and Italy from those of France, even from those which, from their cheapness, must be considered as belonging to the same class, than the various disgusting flavours which they commonly present. Wines may have bad qualities from other causes,—from the nature of the soil or the grape; but there is far less difference in this fruit in different countries than there is in the care bestowed on the manufacture. To use a short and intelligible term, it is *filth* which is the cause of the bad quality of these wines; filth and neglect in every stage of the process, from the gathering to the pressing, the fermentation, and the tunning. In the fermentation, no precaution too great can be used to have all the vessels clean, and entirely free from every odour. There is no substance more delicate than wine, nor any one which is so easily contaminated and destroyed by bad flavours, even in the minutest quantity.

The same rules apply to the casks as to the vats. New casks communicate the well-known flavour of oak, often found in wines, and that, fortunately, is so agreeable that it is often given designedly by means of oak shavings. But in the finer wines, where it would be injurious, it is extracted from the wood by washing, and by hot water and by salt. The more destructive evil of musty vats or casks, so often a cause of the nauseous flavour of the common wines above mentioned, is remedied by scraping, by washing with boiling water, and most effectually by firing or charring the insides; while staves which are deeply injured are replaced by new ones. Hot lime and water are also used for the same purposes.

Another precaution is that of removing all the insoluble matter, of whatever nature, during every stage of the process; and from this neglect it is also that the great mass of bad wines is produced in those countries where this art is neglected. Thus the seeds are always to be removed as fast as they rise to the surface, as they both render the wine harsh and communicate a bad flavour. The same is done with the husks when they have performed their duty in giving out their colour. It is most peculiarly necessary to be watchful over these, lest they should become moulded or musty; whence often arises that taste which resembles that of what is called *corked* wine; a disease also arising from a bad cask, and often attributed wrongfully to careless bottling. In the finer wines, a single musty seed or husk will ruin a whole tun. In transferring the wine from the vat to the cask, or from one cask to another, whether by drawing off or pumping, care must be taken not to disturb the sediment, and more especially still, to separate any of the scum which may be on the surface, as this is always in danger of becoming musty, more particularly where it is most injurious, that is, in the lighter and finer wines.

When the quantity of the fermented fluid is considerable, the remaining wine, which adheres to the solid matter, is separated by the press, and made into wine of an inferior quality, either for use or distillation. That refuse is also subjected to distillation with water in some cases; sometimes, by means of water, it is converted into vinegar, or used for the manufacture of white-lead or of verdegris; or, lastly, formed into cakes with the other refuse of the first pressing of the grapes, and used for feeding cattle.

Management after fermentation.

If, after the wine is made and tunned, it were suffered to go on fermenting, it would in many cases be destroyed. This, it has already been seen, does not easily happen in the sweet wines, where a large portion of the saccharine matter remains unchanged, though even these are not absolutely exempt. Nor does it very easily happen in the stronger dry wines. Yet it does happen to all, and is almost inevitable in the light still wines, and in the brisk ones, whatever the strength or sweetness of the latter may be. Champagne would quickly become vapid, Burgundy would become stale and sour, and Claret would become vinegar. For though the natural progress is supposed to be from the vinous to the acetous stage of fermentation, there are phenomena in practice which show us that we are yet imperfectly acquainted with the exact nature and varieties of fermentation. Champagne, for example, becomes mucilaginous and flat; while, though Burgundy becomes acid, it is scarcely possible to make it pass to the exact state of vinegar.

Yet the tendency to the acetous stage must be considered as general, for want of a better expression; and on this view the management after the great fermentation is regulated. If it is suspected that even intended sweet wine has been overwrought, boiled must or sugar is added to it, and thus, in the tedious fermentation of the cask, it is secured or restored. But it must be remarked, that if the acetous stage should have commenced, that addition would only serve to accelerate and determine it. The remainder of the general management consists in regulating the fermentation of the cask by the general principles before laid down; that is, if the wine is incomplete, it is not suffered to rise to the bung-hole, so that the new leaven which is disengaged may fall back again and protract the fermentation, while this is also aided by heat, by stirring up the lees, and by agitation. If the reverse be the case, and it is necessary to check the secondary fermentation, then a cool temperature and rest are adopted; while, as fast as the wine wastes, it is kept close to the bung by fresh additions, that so the disengaged leaven may escape. Some of the other requisites to the completion of wine will fall better into another section of this little essay; but the process of sulphuring belongs to the second stage of management, as well as to the final operations of the manufacture.

Fining, sulphuring, and clarifying wines.

However vulgar and mechanical the process of sulphuring may appear, it is a refined chemical operation, the practice of which was long known before the theory, however discovered, and the theory of which, in a scientific and rigid view, is not very well understood even now. It has been already shewn, that the process of fermentation has a perpetual tendency to continue as long as all the requisites are present, and more particularly as long as there is present that peculiar and obscure substance, the extractive matter or leaven, on which it mainly depends. If this substance has been entirely separated in the two forms of yeast and lee, the process terminates naturally, the produce being dry or sweet, according to other circumstances now understood; but if any portion of leaven remains in the liquor, then the acetous or some similar stage may come on, and the wine will be destroyed.

The processes of racking and mechanical separation just described, are all intended to separate this matter; and whenever the wine remains turbid, it is always in danger, because the fermentation may at any time be renewed. But these operations are often insufficient to disengage all the leaven or lee, as much of it not only continues mixed, so as to produce the turbid state, but the extractive matter itself, which has not been brought to this insoluble form, remains combined with the fluid.

The merely turbid state is remedied by the process called fining, which precipitates all the insoluble or disengaged lee and leaven that will neither subside nor rise; thus removing one part of the hazard, besides communicating that brightness and beauty which is demanded in all wines. That brightness, therefore, is more than a beauty, since without it there is no security, at least in the finer and lighter wines. Various substances are used for this purpose, and the action of many of them is very obscure. They are either chemical or mechanical. The mechanical substances are sand and gypsum, both of which have the property of precipitating the insoluble matter, while the latter also absorbs water. Beechwood chips are sometimes used for the same purpose; but the mode in which these act is not known. But the matters chiefly in use are chemical ones, gluten and albumen. Of the latter, eggs and milk are both used, but the former are preferred. Of gluten, isinglass alone is used; for, from some causes hitherto undiscovered, the gluten of terrestrial animals, or common glue, does not produce this effect to the same extent that it is obtained by the glue of fishes. It is also usual to adopt albumen for the white wines, and gluten for the red, as the former is found to precipitate much of the colour from these last. The proportion used is very small, an ounce of isinglass being sufficient for a hundred gallons. To these chemical matters we might have added starch, gum, rice, and blood; but they are very little used. The action of the albumen appears more mechanical than chemical; becoming coagulated, and then entangling the dust, if it may so be called, which is suspended in the fluid, in the same manner as it would purify muddy water. In the case of the gluten, however, a new chemical combination is formed with the tannin of the wine; and the produce is that well-known substance resembling bird-lime, which is the basis of leather. Hence, also, fining diminishes the astringency of red wines.

Presuming that one of these substances has been introduced, the fluid is strongly agitated, and suffered to repose till clear, when it is again racked into a fresh cask. It is found very important to select for this purpose dry cold weather, and, as is particularly remarked, north-east winds. From some mysterious cause, in close weather, and fogs, and southerly winds, the precipitated matters rise again, and defeat the objects of the operation. The other precautions are those of using a syphon instead of a cock, as affording greater security; or, what is now used in all the best French manufactories, blowing off. This is performed by a condensing engine, as in the drawing of porter, and thus access of air is prevented. This is very important where fine-flavoured wines are concerned, as it is in brisk wines; because the carbonic acid which would be lost, carrying away also a portion of the alcohol or strength of the wine, is thus preserved.

But the leaven held in solution cannot be separated in this manner, and for that purpose recourse is had to the process of sulphuring. The most common and the simplest practice in this case, is to fill the proposed cask into which the wine is to be racked, with sulphurous gas, by burning matches in it till full. The wine being then introduced, becomes turbid, and, after the necessary time, it is found as before. Should the fermentation still be renewed or dreaded, this operation is repeated as often as it may be necessary. If, as in the case of some of the Bordeaux wines, the quantity of leaven in the wine is so great that it cannot be overcome in this manner, the combustion of the sulphur within the cask is repeated at intervals during the process of filling it. But it is also a practice in that country to impregnate with sulphurous acid a quantity of wine, and this substance or mixed fluid, called *Muet*, is reserved for adding to those which may require it, by which means the efficacy of the operation is better insured.

The theory of this practice seems to a certain extent simple. The sulphurous acid, or possibly its oxygen, unites to the extractive matter, or the soluble leaven, and renders it insoluble, as happens in the act of fermentation itself; and thus it becomes capable of being separated by the mechanical processes of racking and fining. It is for this reason also that sulphuring is largely used for the sweet wines, to insure their preservation in that state. It has been said that manganese, and other substances containing much oxygen, will produce the same effect; but the cheapness and simplicity of the common process renders other expedients unnecessary.

Supposing wines of any class to have been thus obtained, there is yet much more to be done before they become the wines which we know in our market. The processes in use for making marketable wines are badly distinguished by the term medication, as they are of various natures. There is indeed a great deal of wine which can scarcely be considered as strictly natural, though it is a common prejudice that all wines are so, except when fraudulently mended, or altered, or mixed. It is difficult to draw the line between what may be considered fraud, and what is legitimate; and certainly by those who expect that all wine is to be what it is commonly thought, the mere produce of the grape, and of one process on one grape, every subsequent process may be esteemed a fraud. We must here limit ourselves to some of the most important operations, as the whole would lead into a very long detail.

The simplest process is that of mixing different wines together, whether of the same quality or country, or of different ones. In either case this practice may sometimes be considered fraudulent, and in the latter especially so. But in a degree it is inseparable from the nature of the manufacture, and the mode in which it is conducted. The larger maker, or the capitalist on the spot, buying in small lots from the petty manufacturers, is obliged to adopt this practice, partly to insure a certain quality, and partly for the purpose of remedying those that are defective, by the addition of better ones.

The mode of performing this operation, which requires great experience and judgment, is to select, first, that period of the year in which the wines show a disposition to renew their fermentation, which is in the spring. They are then said, in English, to bear the *fret;* and hence the operation is called fretting-in. It is only thus that a new and *fine* wine can be produced. The operation of mixing different wines in all cases disturbs both, so that they become foul. They also tend to ferment again, till a new balance of all their principles is produced; and thus it is expedient to accelerate and determine this fermentation, so as to form a proper compound, without which the new wine would be perishable. After this, also, it becomes necessary once more to have recourse to sulphuring, fining, and racking; and not till all this has been gone through is the wine completed. In the Bordeaux practice of mixing Clarets, the muet or sulphured wine is sometimes added at the same time, where the wines being of very discordant qualities, a dangerous fermentation might be excited.

In the wine-countries it is usual to cultivate particular grapes or wines, rough, or coloured, or astringent, or high flavoured, for the mere purpose of mixing with others; so far is this art from being so simple as is commonly imagined. It is a frequent practice to import the wines of one country to mix with those of another, and thus to suit the taste of purchasers, or obtain other ends. This practice is pursued even by the importers into Britain, and, as we need not say, opens a door to endless frauds, while it may also be innocent. Thus, in this country, as well as in Portugal, the wines of Spain, Alicant, Barcelona, and so forth, are mixed with Port wines; as are the cheaper Clarets of the south of France, and some other of the strong-flavoured wines of that country. In a similar manner, the wines of Fayal and the Canaries are manufactured into Madeira, as are those of Sicily; and thus, too, Sherry is largely compounded out of many of the wines of Spain and Portugal, and of the islands of the African coast.

But the most extensive operations of this nature are carried on at Bordeaux with the wines which we call Claret, not one-thousandth part of which are of a good quality, or unmixed in some way, and the one half of some of which, perhaps, are not French, but Spanish wine. The following statement, while it is curious in itself, will illustrate this subject. In the year 1814, the total quantity of the Clarets, or Bordeaux of the first class, was as follows:—

	Chateau Margaux	80 tons.
	Latour	70 ...
	Chateau Lafite	80 ...

In the second class it was thus:

Margaux de Madame Derauzan		60 tons.
	M. Chevalier	25 ...
	M. Monterison	25 ...
	M. Montalambert	25 ...
St Julian	Leoville	80 ...
	Lanoze	70 ...
Pauillac	M. Depichon	60 ...
	Brame Mouton	80 ...

We cannot afford room for the remainder of this statement, comprising the produce of the fourth and the fifth qualities; but it is plain that very few of those persons who imagine that they are drinking the first growth of Bordeaux wines, can even be drinking the second.

The first growth of Claret, it is thus seen, amounts only to 230 tons for an average; and that even of the second is only 425; a fraction indeed in the consumption of Europe. But in the third class, of which we cannot afford to give the details, there are 1061 tons, and in the fourth 825, making a general total of 2541 tons. Besides this, there are other inferior wines which do not enter into the enumeration; and it is by mixing the greater number of these in various proportions that the market is supplied, it being necessary to reserve many of the better wines to render the others saleable.

We must however remark, that, among the districts which produce the inferior wines, such as those of the Bas and the Petit Medoc, a few farms produce small quantities, of a quality equal nearly to the good St Julian or Lafite wines; and these add to the bulk of the better kinds, being generally reserved, and sold at high prices. In the district Medoc, the seat of the better wines already mentioned, there are, besides the third and fourth classes, six or eight kinds of wine, known by the names of *Gros Bourgeois*, *Petit Bourgeois*, *Artisan*, and *Paysan;* and these are manufactured, with others, for the British market chiefly, by means of Spanish wines, by mixing with the strong wines of Benecasto and Alicant. The same is true of the Grave wines.

This is the great mixture, in fact, by which the market is filled to almost any extent with Claret wines so called; and these mixed wines are almost the only ones we drink in this country. If that be a fraud, it must also be remembered that such is British taste in wine, and that Claret is generally esteemed here only in proportion to its strength. Of the stronger and finer wines there is not enough for even our consumption; and as we must have them strong, they are rendered so by this process. That effect is also obtained, however, by some of the south of France wines; by those of Côté, which are used for mixing with the weak Medoc and Grave wines, for the British market. This is the case with those of Queyries, such as Monferrant and Bassens; and those of Palu, such as Macaw, St Romain, Codillac, St André, Lugon, and many more.

Mixture of brandy.

The French wines of which we have been speaking will not endure to be rendered stronger by means of brandy. The property of this substance, thus mixed, is to decompose the wine in process of time, causing the extractive matter or mucilage to be deposited, as well as the colour, as is daily seen in Port wines, and thus diminishing their powers of duration. At the same time it destroys their lightness and flavour, that peculiar indefinable delicacy well known to drinkers of good wine, but quite imperceptible to British drinkers of Port. In a certain sense, we may consider that it is only the bad wines which will bear this medicine; those which have no flavour of their own, and whose whole merit already is their strength. What sort of a compound is made of a weak wine with brandy, ought to be known to those who drink what is called Lisbon wine. But a depraved taste has rendered it necessary to our nation, and thus it is largely used, even in those wines of Portugal and Spain, of which the chief fault is that of being too strong already. We may thank the Methuen treaty for being condemned to drink what Mr Pinkerton calls wine fit for hogs only. This mixture is performed in the same manner, at the period of fretting; and the proportion is regulated partly by the taste of the consumers, and partly by the badness of the wine. As it must have a certain strength, the worst wines require most; and hence, whenever we taste the brandy in wine, we may be sure it is bad. It is a taste sufficiently perceptible to those who know what real wine is.

Flavouring of wines.

Many wines have naturally so little flavour, that they can scarcely be considered to possess any. There are few indeed that possess this quality in any great degree; and of these flavours a large proportion is bad. Wines so highly perfumed by nature as Hermitage and Burgundy are rare; indeed these are almost the only examples; and after them we may consider the finest Clarets, and then the finest of the Rhine wines. The sweet wines which possess it are well known; and these also are but a small part of the total number in this class, being almost limited to Paxaret and the Muscat wines, among which Rivesaltes stands first. Constantia has rather a taste than a flavour; and what the ordinary sweet Spanish wines possess is rather bad than good, though, like the taste of Sherry, and porter, and olives, they may become agreeable by habit.

Excepting these cases, and a few among the Italian wines, which we cannot afford room to detail, many of the flavours found in wines are communicated by art; and this forms part of the business of the manufacturer and merchant. Much of this is a secret, but some of the substances used for the purpose are known. The taste of Greece is now, as it was in ancient times, to perfume its wines with turpentine—the *vina picata* of the ancients; and this is effected by putting turpentine or rosin into the casks. In Britain our chivalrous and baronial ancestors perfumed their wines with every strange ingredient that can be imagined; but that was the age of spicery and perfumes, and he who ate cinnamon with his pork, might drink ambergrease in his wine.

The flavour of Madeira is nothing but that which we know is given by means of bitter almonds, and we believe of sweet almonds also; and the same practice is followed for the wines of Saint Lucar. That which is called the *borrachio* taste in wine is for the most part that of the tar with which the seams are secured. In Sherry the flavour seems produced by the destruction of the acid, the consequence of the lime used, and possibly by some other action of that substance on the fruit. One of the most common ingredients used for flavouring wines is oak chips; and from this the wretched Lisbon wines acquire the little taste they have. Orris root is also a common ingredient, and the high-flavoured wine of Johannesberg is imitated by a proportion of rose-water. The orris root gives a very agreeable flavour, and is used in France; and there it is also the custom to use raspberries and other highly perfumed fruits. A very agreeable flavour is also said to be produced by wormwood. The flowers of the vine itself are likewise used for the same purpose, their smell much resembling that of our mignonette. This last is an ancient practice in Egypt.

The method of gaining this end requires some delicacy and attention. In particular, care is taken that it be not overdone. As the full fermentation would destroy the more volatile flavours, these substances are only introduced towards its decline. In Madeira the nut-cake is put into the cask. Flowers are suspended in a net or cloth, either in the fluid or the vacant part of the cask, and thus a small quantity of raspberries communicates a considerable flavour.

Colouring of wine.

The colouring of wine is also part of the business of the maker, because colour is in a good measure a matter of fashion and fancy. Some grapes contain naturally very little colour, while that of the Claret vine, and many of the grapes of Spain, are highly charged with the colouring principle. We already explained that the colour was contained exclusively in the husk. These latter wines are often, therefore, selected and reserved for this particular purpose; and it is also a practice to use the dyeing woods, logwood and Brazil wood, for obtaining the same end. The elder-berry, which is full of colour, is also resorted to; and in Portugal it used to be extensively cultivated for the purpose of dyeing Port wines. When white wines are thought too pale for the market, they are coloured browner by means of the well-known ingredient burnt sugar; and the chips of oak also produce the same effect. By some means also iron finds its way into some of the French wines, and thus, on exposure to air, they become black. This unpleasant effect is not unusual in the sweet wines from the south of France.

Briskness of wines.

This property relates almost exclusively to the wines of Champagne, and it is one that may err in excess or defect. It is already apparent that it is the product of an unfinished fermentation, and therefore a due degree of it must mainly depend on the proper management of this process. It is secured by bottling at the proper season, March, and before the fermentation is exhausted; and if in danger of excess, it is restrained or diminished by racking, or decanting and sulphuring. But it happens not unfrequently that it fails altogether, either from accident in the management, or a bad season; from faults in the fruit, or fermentation carried too far, or a weak wine exhausting itself unexpectedly. In this case the remedy is to introduce sugar, not only into the cask, but into the bottles. In the first case the fermentation is renewed, and the wine may thus become legitimate and good. In the other the effect is far different, and not good; and hence it is that all the very sweet Champagne wines are bad or indifferent. These are, in fact, a mixture of wine and sugar rather than proper wine; and in this case the effect of the sugar is not to produce a new fermentation, but to disengage the carbonic acid of the wine, as a salt or any other soluble substance would do by a superior affinity. To gain this end, the solid sugar is corked up in the bottle, so that the disengaged gas is retained under the pressure of the cork, ready to fly out whenever that is removed. Thus Champagne which has been destroyed by age is rendered at once sweet and effervescent; and this, however convenient a secret it may be to the possessor, is but a fraud, and a very common one.

The acidity, or the pricked taste of wines, is a fault which perhaps ought never to be corrected, as in this case the wine is generally spoiled. This nevertheless is done, and sometimes to a considerable extent. Acidity arising from tartarous acid, or even from malic acid, if that really be the acid in wines which is not tartarous, may be a virtue and a quality, as it is very remarkably in Hock. But it is often thought otherwise, even when it is the natural property of the wine, arising from its own native acid, and after a correct fermentation. In this case means are applied to remedy it as a disease in the wine. In the manufacture of Sherry, it was already remarked that lime was used to prevent it; and this is also applied in other cases where tartar is in excess, as the tartrite of lime is insoluble, and can be fined down and separated by racking. It has been the fashion to use lead, metallic lead, for this purpose; and in France it was formerly used largely in the wines consumed in Paris. It was then discovered, and the act made penal; and if not abandoned entirely, it is less used at present everywhere. That this is a poisonous substance is too well known; but that has been overrated in this particular case. The tartrite of lead, like that of lime, is insoluble; so that after the lead had done its duty, it was discharged by racking and fining. Had this not been the case, all Paris, at the time we speak of, must have been poisoned. Yet it is a substance that ought not to be used, because, in an acid wine ascescent from fermentation, it might produce either white lead or subcarbonate of lead, or else sugar of lead, acetite, both of them poisons if in different degrees.

For the acidity of wine from the commencement of the acetous fermentation there is no proper remedy. It may be checked if taken in time, as it would be prevented by careful sulphuring. Here lead is highly pernicious; and it need scarcely be said, that to add sugar of lead, as has been done from ignorance and fraud united, is to add a poison without even obtaining a remedy. Chalk and lime may be used with impunity; yet neither can these, and far less alkalies, be used to such an extent as to cure the disease, as they unite to the other acids, and also decompose and destroy the wine. To prevent it as far as possible when commenced, a low temperature and careful exclusion from the air are necessary. But it must be remembered that air will find access, not merely through cork, but through sealing-wax, and indeed through all rosins also; and thus there can be no complete security, the best being that of placing the bottles on their sides, so that the fluid itself becomes its own cork. The Italian practice of using oil is thus far safer, but it is balanced by various inconveniences.

Ropiness is a disease almost peculiar to the wines of Champagne, and its chemistry is very obscure. It is not a destruction of the wine, although it materially injures its flavour and other qualities. It occurs in this wine from the quantity of extractive matter which it still contains, and which is that by which the fermentation is maintained. It is conceived to arise from the action of oxygen on this substance, converting it into a matter analogous to fibrine, instead of changing the whole into vinegar. Thus it resembles the mucilaginous deposit of vinegar called the *mother*. In the bottles it may be often cured merely by heat, by exposure to the sun, or by immersion in hot water. When obstinate, it is remedied by uncasking and by agitation, by exposing the fluid to the air. It is also said to be removed by a small quantity of vegetable acid, or by sugar; but when on a large scale, it requires the process of fining.

Bottling and cellarage of wines.

It is held essential by the French, who are our chief teachers in every thing that relates to wine, that a wine-cellar should not only be dry, but preserved in a very uniform state of temperature, as near to the mean annual heat of the country as possible. We have already shewn, however, when this rule may be usefully departed from, for the purpose of accelerating the ripening of wines. In the delicate wines of that country the rule still holds good, and very conspicuously too with regard to the wines of Burgundy and Champagne. It is equally true of the finer and lighter Italian wines. The wines of Spain and Portugal seem to defy every thing. It is also held by the French most essential that a cellar should not be subject to the agitation of carriages, the reason of which is plain enough; and that it should be free of bad smells. As to moisture however we must remark, that, like heat, it seems to accelerate the deposition and consequent ripening of Port wines. Of bottling we need say nothing; only let it be remembered that corks cannot be too good, but that no precaution will absolutely prevent all communication through a cork, however secured and sealed.

Making of particular wines.

The rules which we have thus given are all of a general nature; but there are yet a few niceties to be explained, and an example from each of the four classes into which we divided wines will render the subject more intelligible.

Champagne wines.

The attentions required in Champagne wines are perhaps the most minute and the most complicated, and they therefore stand most in need of being detailed. Champagne is a late country, and it frequently happens that the frosts have commenced before the grapes are ripe. Of course it is an imperfect vintage, which limits that country to this particular class of wine. A very brisk wine is not easily secured from grapes absolutely ripe; and thus the half-ripened fruit of this district is brought into use. Yet the best of these wines, the finest class of Sillery, rarely seen in this country, is made from the ripened grapes; and hence it is that the best of the Champagne wines are those which are least brisk or violent, and that great violence is a characteristic of the inferior kinds.

The finest wine is produced here by a very light pressure of the grapes, in which case only the ripest give out their juice. It is held necessary to gather them when the morning dew is off, to prevent water being added to the juice. The next pressure and the least ripe grapes are reserved for the inferior classes. When the juice is poured into the vat, it remains one night only, the seeds being carefully separated. In all cases the greatest care is taken to separate damaged grapes or rotten ones; and it is as much from this neglect as any other cause that the common Italian wines are so bad. If the Champagne is to be red, the fermentation is suffered to proceed on the husks a little longer, for the purpose of extracting the colour; and according to the length of this process, we have the *œil de perdrix*, and the pink and red wines. But, as we remarked before, this injures the flavour, as all good judges of Champagne know.

When the liquor is transferred to the cask, the discharge of yeast at the bung-hole is encouraged for ten or twelve days; and when the fermentation has become moderate, the bung is put down, and a hole is made by its side. This hole is occasionally opened to give vent to the air, for a space of eight or ten days. When no more air is discharged, fresh wine is introduced, so as to keep the cask constantly full to the bung-hole. This operation is continued if necessary till the end of December, when the wine generally becomes clear. It is then racked into a fresh cask, and fined. After this it begins to ferment again, losing a portion of its sweetness, and improving in quality. If too sweet, it is not decanted and fined till the fermentation has been renewed by agitation. As the fineness of this wine is one of its essential qualities, and one difficult to obtain on account of its perpetual fermentation, it is racked and fined a second time, and thus it remains till March. In March it is bottled; yet still it ferments, though corked, and again it begins to deposit. In the best wines it thus remains from fifteen to eighteen months in the cellar, when it is bottled over again, and is then marketable. The inferior kinds are seldom bottled twice, but an expedient is used instead to get rid of the sediment. For this purpose the bottles are ranged in frames with their necks downwards, and when the sediment has been collected in the neck, the cork is dexterously drawn, and again replaced, after which the bottles are filled and completed for the market. There are varieties also in this general process, such as that of suffering the wine to remain in the cask for a year or more on its lees; but we need not enter into these collateral details.

Burgundy and Bordeaux wines.

There is little difference in the practice of Burgundy, except what refers to the retention of the carbonic acid. All else is the same; but great care is taken to clear these wines of their lees, as, from their extreme delicacy, they would soon lose their flavour, and also become sour. In the practice of Bordeaux also the first stages of the process are the same, excepting in as far as a longer fermentation in the husks is used to extract the colour from the red wines. But there is a difference as to the process of sulphuring, which is largely used in these, in the manner already described. The red wines of Bordeaux are racked about the end of March or the beginning of April, but the white in December; and in all these wines great care is taken in all those circumstances which relate to cleanliness, however rude the people and the operations may appear on a superficial view.

Italian wines.

In the drier Italian wines, the must is allowed to ferment completely in the vat. In some vineyards a quantity of selected and half-dried grapes is thrown into each tun when the wine is finished, so as to give it sweetness, and prevent the hazard of its running to the acetous stage; a rude and a bad process. In the manufacture of Florence wine, the must is withdrawn from the vat as soon as the head is raised, and the wine is transferred to a cask, where it is only suffered to remain thirty-six hours, when it is again decanted into a fresh cask at the end of a few hours, and so on until it is clear and marketable. Thus it is completed in a short time by little more than the process of racking.

Sweet wines.

In different countries the practices used for procuring the sweet wines vary, but they will be found to depend on one or other of the principles already laid down. In Italy, as in the making of Florence wine, the fermentation is quelled by repeated racking and shifting. Thus the other processes are partly or entirely saved. But it is necessary that very sweet and rich grapes should be used if this process is to be followed. To insure sweetness, on the principles formerly laid down, the grapes of Tokay are partially dried before they are used; and this is also done for the wines of Cyprus, and for some of those of France and Spain. The remaining processes, consisting in sulphuring, &c., need not again be detailed, as they are nearly the same in all countries.

Port, Madeira, &c.

In Oporto, for the dry wines, the practice is to carry on the complete fermentation of the must in the vats. The wine is then introduced into large tuns, capable of holding twenty-five pipes each, and at this stage the brandy is added at the discretion of the maker. In Madeira, the second or insensible fermentation is effected in pipes; and at the end of three months the wine is racked, when a certain portion of brandy is added. In both these practices it would seem as if the union of the brandy with the wine was less perfect than it might be rendered by a different management of this part of the process. Hence probably it arises, in a great measure, that the taste of brandy is so sensible in many of these wines. In the best, the quantity is said to be about a twentieth part; but in the worst class of Port wines it seems sometimes to amount to a fifth or more. The process followed in making Sherry is rather more complicated. The grapes in this case are first slightly dried, and then sprinkled with quicklime. They are then wetted with brandy when introduced into the press, and a further portion is again added to the must before fermentation. It is highly probable that by this practice the brandy is more perfectly combined in the wine, and the fluid rendered more uniform; and hence also probably it arises that the taste of brandy is not to be perceived in genuine Sherry, though often found in those baser imitations which are manufactured from the tasteless wines of the Canary Islands, and of other parts of Spain. The remainder of the process for Sherry consists in racking repeatedly, at intervals of a month or two, fresh brandy in small quantities being added at each stage of this process.

In conclusion, we remark, that in the attempts to make wines in our own country from native fruits, the same rules are of universal application, and that an attention to them would render these domestic processes more complete than they now are, and the results more valuable. In Britain also it is easy to make very good wine from immature grapes, by the addition of sugar in the necessary proportions; and these can be procured in almost any season, so that this might even become an object of a petty domestic commerce. Nor is the manufacture limited to the fruit alone, since the leaves and tendrils, by infusion, admit of the same treatment, and with the same results. Very tolerable wine, perfectly resembling the wines of France, can thus be made, and at an expense of little more than the very moderate cost of the sugar. (Z. Z. Z.)

The following table shows the number of gallons of foreign wine imported into the united kingdom, the quantities upon which duty has been paid for home consumption, and the quantities exported; also the quantities retained for home consumption, after deducting the amount exported subsequently to the payment of duty; for the year ended the 5th January 1841.

WINGHAM, a small town of the county of Kent, in the hundred of the same name, and in the lathe of St Augustine, sixty-two miles from London. A convent was founded here in the reign of Edward I. by Archbishop Peckham. Near to it are some fine gentlemen's seats. The population amounted in 1821 to 1085, and in 1831 to 1115.

WINKELMANN, John, was born at Stendall, in the old Marche of Brandenburg, in 1718. He was the son of a shoemaker. This wonderful man, to all appearance destined by his birth to superintend a little school in an obscure town of Germany, raised himself to the office of president of antiquities in the Vatican. His course of study appears to have been very desultory, but he spent two years in the university of Halle. After having been seven years rector of the school of Seehausen, near Salswedel, he went into Saxony, where he resided seven years more, and was librarian to Count Bunau at Nothenitz. When he left this place, 1754, he went to Dresden, where he formed an acquaintance with the ablest artists, and particularly with Oeser, an excellent painter, and one of the best draughtsmen of the age. In that year he abjured Lutheranism, and embraced the Romish religion. In September 1755, he set out for Italy, and arrived at Rome in December following. His principal object was to see the Vatican library, and to examine the ruins of Herculaneum.

Winkelmann carried with him into Italy a sense of beauty and art, which led him instantly to admire the master-pieces of the Vatican, and with which he began to study them. He soon increased his knowledge; and it was not till after he had thus purified his taste, and conceived an idea of ideal beauty, which led him into the greatest secrets of art, that he began to think of the explanation of other monuments, in which his great learning could not fail to distinguish him. In 1756 he planned his Restoration of Ancient Statues, and a larger work on the Taste of the Greek Artists; and he designed an account of the galleries of Rome and Italy, beginning with a volume on the Belvidere statues, in the manner of Richardson, who, he says, only ran over Rome. He also intended a history of the corruption of taste in art, the restoration of statues, and an illustration of the obscure points of mythology. All these different essays led him to his History of Art, and his "Monumenti Inediti." It must however be confessed, that the first of these works has not all the clearness and precision that might be expected in its general plan and division of its parts and objects; but it has enlarged and extended the ideas both of antiquaries and collectors. The description of the gems and sculptures of the Stosch cabinet contributed not a little to extend Winkelmann's knowledge. Few persons have opportunities of contemplating such vast collections. The engravings of Lippet and Count Caylus are all that many can arrive at. Winkelmann's "Monumenti Inediti," of which he had begun the third volume in 1767, seem to have secured him the esteem of antiquaries. Had he lived, we should have had a work long wished for; a complete collection of the bas-reliefs discovered from the time of Bartoli to the present, the greater part of which were in the possession of Cardinal Albani.

When Cardinal Albani succeeded to the place of librarian of the Vatican, he endeavoured to procure a place in the Hebrew department for Winkelmann, who refused a canonry because he would not take the tonsure. In 1761 the elector of Saxony gave him, unsolicited, the place of Counsellor Richter, the direction of the royal cabinet of medals and antiquities at Dresden. Upon the death of Venuti, 1762, he was appointed president of the antiquities of the apostolic chamber, with power over all discoveries and exportations of antiquities and pictures. This is a post of honour, with an income of 160 scudi per annum. He had a prospect of the place of president of antiquities in the Vatican, about to be created, at sixteen scudi per month, and was named corresponding member of the Academy of Inscriptions. The king of Prussia offered him, by Col. Quintus Icilius, the place of librarian and director of his cabinet of medals and antiquities, vacant by the death of Gautier de la Croze, with a handsome appointment. He made no scruple of accepting the offer; but when it came to the pope's ears, he added an appointment out of his own purse, and retained him at Rome.

In April 1768, he left Rome to travel with Cavaceppi over Germany and Switzerland. When he came to Vienna, he was so pleased with the reception he met with, that he made a longer stay there than he had intended. But being suddenly seized with a secret uneasiness and extraordinary desire to return to Rome, he set out for Italy, deferring his visits to his friends in Germany to a future opportunity. As he passed through Trieste, he was assassinated, June 8, 1786, by a wretch named Arcangeli, a native of Campiglio, a town in the territory of Pistoia, with whom he had formed an acquaintance on the road. This miscreant had been condemned for a robbery to work in fetters four years, and then to be banished the Austrian territories on an oath never to return. He had obtained a mitigation of one of his sentences, and retired to Venice; but changing his quarters backwards and forwards, he was so reduced in circumstances that he at length took up his lodgings at the inn where Winkelmann happened to arrive. Arcangeli paid such assiduous court to him, that he entirely gained his confidence; and having been favoured with a sight of the valuable presents which he had received at Vienna, formed a design to murder and rob him. He bought a new sharp knife on purpose; and as Winkelmann (who had in the most friendly manner invited him to Rome) was sitting down in his chair, early in the morning, he threw a rope over his head, and, before he could disengage himself, stabbed him in five different places. He had still strength to descend to the ground-floor and call for help; and being laid on a bed in the midst of the most violent pain, he had composure sufficient to receive the last sacraments, and to make his will, in which he appointed Cardinal Albani his residuary legatee, and expired in the afternoon. The murderer was soon after apprehended, and on the 20th of June was executed on the wheel, opposite the inn where he had committed this atrocious deed.

WINSLOW, a market-town of the county of Buckingham and hundred of Cotslow, fifty miles from London. It is neat and well built, has a market on Tuesday, and its population amounted in 1821 to 1221, and in 1831 to 1290.

WINTER, one of the four seasons or quarters of the year. Winter commences on the day when the sun's distance from the zenith of the place is greatest, and ends on the day when its distance is at a mean between the greatest and least. Under the equator, the winter, as well as other seasons, returns twice every year, but all other places have only one annual winter; which in the northern hemisphere begins when the sun is in the tropic of Capricorn, and in the southern hemisphere when in the tropic of Cancer; so that all places in the same hemisphere have their winter at the same time.

WINTON, Andrew, prior of Lochleven, appears to have been born during the reign of David the Second, which extended from 1329 to 1370. For the few scattered notices of him that have been preserved, we are chiefly indebted to the valuable work which has transmitted his name to posterity. Of his parentage and education no record has hitherto been discovered; but we learn from his prologue that he was a canon regular of St Andrews, and prior of the monastery of St Serf. The priory of St Andrews was endowed with very ample revenues; and the prior, in consideration of his connection with the metropolitan cathedral, was entitled to take precedence of all priors, and even of all abbots. There were five subordinate priories belonging to St Andrews; namely, those of St Serf in the *inch* or isle of Lochleven, Portmoak on the northern bank of the same lake, both in the county of Kinross, Pittenweem in the neighbouring county of Fife, the isle of May near the termination of the Firth of Forth, and Monymusk in the county of Aberdeen. In the isle of Lochleven there was a very ancient religious house belonging to the Culdees, for whom the canons regular of St Augustin were afterwards substituted by the bishop of St Andrews. The beautiful and romantic situation of this priory furnished a very suitable abode for a poet; and here Winton must chiefly have resided during a considerable part of his life. In the Chartulary of the Priory of St Andrews, which is now printed, there are several documents bearing the name of Andrew Winton as prior of Lochleven between the years 1395 and 1413; but his life must have been prolonged several years after this last date, for he mentions the death of Robert duke of Albany, an event which happened in 1420. In the prologue to the last book of his chronicle, he expresses his anticipation of a speedy dissolution.

His Orygynale Cronykil of Scotland was undertaken at the suggestion of Sir John Wemyss, ancestor of the noble family of that name.

> This tretys sympylly
> I made at the instans of a larde
> That hade my serwys in his warde,
> Schyr Jhone of the Wemys be rycht name,
> Ane honest knycht and of gude fame.

Winton's chronicle, while it yet remained in manuscript, was not entirely neglected by more curious enquirers: it was quoted by Selden, a writer of prodigious research, who was not however acquainted with the author's name; it afforded some useful information to Ruddiman for his edition of Buchanan, and to Innes for his Critical Essay on the Ancient Inhabitants of Scotland; nor was it completely overlooked by Lord Hailes and Mr Pinkerton. Of that portion which relates more immediately to Scotish affairs, a splendid edition was at length published by the late David Macpherson, who has added a copious glossary, a series of valuable annotations, and other useful appendages.[1] It may safely be affirmed that none of our ancient writers has yet been edited in a more faithful and judicious manner. The basis of his text is the Royal MS. in the British Museum: this appears to have been transcribed for George Barclay of Achrody, and its date is supposed to be at least as early as the year 1430; but he likewise had recourse to several other manuscripts, belonging to the same institution and to the Advocates Library.[2]

The chronicle of Winton is valuable as a specimen of the literary taste and attainments of our ancestors at a very remote period, but it is still more valuable as a repository of historical information, and as a delineation of ancient manners. His simple pages present to our view many curious prospects of society; and with a perseverance of industry which had numerous difficulties to encounter, he has collected and preserved many anecdotes that tend to illustrate the history of his native country. He divides his work into nine books, "in honour of the orders nine of holy angels." Although he merely professes to write an original chronicle of Scotland, yet, like other Gothic chroniclers, he presents his readers with an outline of the ancient history of the world. Towards the beginning of his work, he treats of the nature of angels, the creation of the world, the death of Abel, the generations of Cain and Seth, the primeval race of giants, the situation of India, Egypt, Africa, Europe, Britain, Ireland, and divers other countries, the confusion of tongues, and the origin of poetry and idolatry. One chapter he devotes to the history of the Amazons, and another to that of Samson. After commencing in so hopeful a manner, he continues to amass an immense pile of lumber, till having completed five books in this pantographical spirit, he at last confines himself more soberly to his proper subject. The adoption of such a plan is not to be considered as peculiar to the author: Winton follows the models which at that period were generally approved; and the Latin chronicle of Fordun, who was nearly contemporary, is composed of the same heterogeneous materials. (x.)

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answering to the hole it passed through. Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c. The metals most commonly drawn into wire are gold, silver, copper, and iron. Gold wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller, till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is nowhere more conspicuous than in this gilt wire. A cylinder of forty-eight ounces of silver, covered with a coat of gold only weighing one ounce, as Dr Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence ninety-eight yards of the wire weigh no more than forty-nine grains, and one single grain of gold covers the ninety-eight yards; so that the ten thousandth part of a grain is above one eighth of an inch long.

WIRSWORTH, a market-town of the county of Derby, in the hundred of its own name, 139 miles from London and twelve from the town of Derby. It is situated in a mining district, where it is the chief object to procure lead ore, and the silver frequently combined with it. The principal occupation is connected with the various processes of preparing these metals for use. There are laws regulating the mining, which are here administered by a court consisting of a steward and bar-mast, which has two sessions annually. In the neighbourhood, many millstones and grindstones are drawn from the quarries. Here are two springs, one hot, the other cold, so near together that a man may put a hand in each at the same time. There is a good market on Tuesday, and two fairs yearly. The population amounted in 1821 to 3787, and in 1831 to 4082; but the parish comprehends ten hamlets and townships besides, whose inhabitants amounted in 1831 to 7754.

WISBEACH, a town of the county of Cambridge, in the Isle of Ely, eighty-nine miles from London. It is a port, standing on a branch of the Ouse communicating with Lynn. The country around is rich, producing much corn, a great part of which is sold at the market, and afterwards shipped to other parts of the kingdom. The sessions for the Isle of Ely, which is an exempt jurisdiction, are held at this place. It is deemed unhealthy. The population amounted in 1821 to 6515, and in 1831 to 7253.

WISBY, a city of Sweden, the capital of the province and island of that name, or, as it is sometimes called, Gottland. It is situated on the western side of the island, was formerly a Hanse town, and a place of great trade. It is fortified, is rather irregularly built, but of stone, and in the style of the ancient German seaports. The harbour is not

[2] Of Winton's chronicle a considerable number of MSS. is mentioned by Macpherson, but several others are known to be preserved. There is one in the Lansdowne collection, lately added to the British Museum, another in the library of the university of St Andrews, and a third in that of Captain Wemyss of Wemyss.

n. dec, and is very small; but it still has some ships belonging o it. It contains 700 houses, with 3880 inhabitants. Ne to it are some quarries of marble. Long. 18. 2. 29. E. at. 57. 38. 30. N.

ISCONSIN. The vast tract under this name, erected int a territory of the North American Union, stretches fro Lakes Michigan and Superior to the Missouri and W te Earth Rivers, and from the northern frontier of the Mi ouri and Illinois to the boundary between the Ame-ric and British possessions; extending from 40° 30′ on the west of the Mississippi, and 42° 30′ on the east of tha river, to 49° north latitude, and from 87° to 97° west lon tude in the south, and from 90° to 102° in the north. It about 580 miles in extreme length from north to sou, and varies from 300 to 600 in breadth, with an area of bout 275,000 square miles. The greater part of the ter ory is still owned and occupied by Indian tribes, and a ge portion of its surface has not been explored by wh es.

general description of the surface and soil of this vast tra , exceeding in dimensions by one third the whole king-do of France, can be applicable to all portions of it. It is art of the great central table-land of North America, ha ng a general elevation from 800 to 1200 feet above th evel of the sea; and probably the loftiest mountains in e territory do not rise more than 2000 feet above th general level. The northern portion of the section we of the Mississippi is traversed by a broad ridge, pre-se ng few irregularities of surface, and attaining no great ele tion, although it forms the water-shed between the Mis-sou and the Mississippi. Its elevation is only about 500 or 00 feet above the level of the adjoining country. It is the most part destitute of trees, but contains nume-ro lakes, with some wooded patches. There is said to be nother ridge between this and the Missouri, but infor-ma on as to this whole section is very scanty. A low ridge of ne-covered hills runs between the sources of the Mis-sis pi and the tributaries of the Red River; and a similar ri e divides the waters of Lake Superior from those of the M issippi and Hudson's Bay. Another hilly tract stretches fr the head of Rock River to Lake Superior, between th Fox and Menomonie Rivers on the east, and the Chip-pe a and Bois Brulé on the west, to which has been given th name of Wisconsin or Porcupine Hills. Lead has be found on the southern part of this tract, where the O och and Smoky Mountains are about 1200 feet above th general level; and copper occurs in the north. By fa he greater part of the territory is prairie or unwooded co try. Farther north, between Lake Superior and Red Ri r, is a region of lakes, swamps, and savannahs, or wet pr ies, overgrown with sedges and rushes, which may well be alled the great source of waters, since it gives rise to ri s reaching the Gulf of Mexico, Hudson's Bay, and the G of St Lawrence, at points from 1200 to 2000 miles di nt from this common centre. Much of the soil in the no hern part is inferior, and unsuitable for cultivation; but on he south the general features of the country resemble th e of the adjoining states. That portion of the Upper M issippi lying between the junction of the De Corbeau an St Anthony's Falls, presents to the eye a succession of pr ie and forest land, which has the general charac-te tics of a valuable agricultural country. The soil is ar le, and apparently light, but of that ferruginous charac-te which has turned out so durable and fertile in Michi-ga Wood is often wanting, though forests may be ob-se ed on the hilly grounds. Wild hay may be cut in any qu tity. The tract here described is included in the re-ce cessions of the Chippewas and Sioux. Although there ar many marshy and barren tracts, yet the rapidity with wh h this region has been lately filling with settlers is a pr f that it contains much land of a superior quality. The southern section of the western district, on the Desmoines and the Iowa, is believed not to be surpassed in fertility by any portion of the United States; and although consisting mostly of prairie, contains woodland enough for economical purposes.

Wisdom
||
Wit.

The Mississippi forms the most striking natural feature of the country. Its most remote source, as has been recently ascertained by the expedition conducted by Mr Schoolcraft and Lieutenant Allan, is the little lake called Itasca by the Indians, and La Biche or Elk Lake by the Canadian traders, 3160 miles from the Gulf of Mexico, and 1029 from the Falls of St Anthony. The lake is estimated by Mr Schoolcraft to be at an elevation of about 1500 feet above the level of the sea, and is separated from the tributaries of the Red River by the low ridge of hills called by the voyageurs Hauteur des Terres. The rivers in this territory are numerous, and mostly flow into the Mississippi. The Wisconsin, which joins it at Fort Crawford, is one of the most important of its tributaries. It is 550 miles long, and is navigable by steam-boats for about a hundred miles from its junction with the Mississippi.

The settled portion of the territory is divided into twenty-six counties, of which eight are in the western or Iowa section, and eighteen in the eastern or Wisconsin section. The area of the former is about 12,500 square miles, the population at the close of 1837 probably exceeding 20,000; the latter has an area of about 20,000 square miles, with about 30,000 inhabitants. But this extensive region is chiefly inhabited by numerous and powerful tribes of Indians, among whom attempts have been for some time making to introduce the arts of civilized life. Missionaries and teachers have been stationed in various districts, by the different religious societies.

The government was organized in 1836. The legislative assembly consists of a council of thirteen members, elected for four years, and a house of representatives, elected for two years. In 1838, there were published in this infant state three weekly and one monthly newspaper.

WISDOM usually denotes a higher and more refined notion of things or qualities immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination. Sometimes the word is used, in a moral sense, for what we call *prudence* or *discretion*, which consists in the soundness of the judgment, and a conduct answerable to it.

WISMAR, one of the provinces into which the grand duchy of Mecklenburg-Schwerin is divided. It belonged to Mecklenburg till 1648, when it was delivered over to the Swedes, who possessed it till 1803, when it was transferred for a sum of money to the present sovereign. It is situated on the Baltic Sea, and, including the island of Poël, extends over thirty-eight square miles, or about 25,000 acres, and comprehends one city and thirty-seven villages, with 15,419 inhabitants. The capital is the city of the same name, situated on a bay of the Baltic. It is surrounded with walls and ditches, contains four Lutheran churches, three hospitals, an orphan-house, and several schools, 1350 houses, and 10,070 inhabitants. It has some foreign commerce, especially in the export of wheat and other grain; and has several ships annually equipped for the whale-fishery. There are manufactures of linen goods, especially of sailcloth, with several breweries and distilleries.

WIT is a quality of certain thoughts and expressions, more easily perceived than defined. According to Locke, wit lies in the assemblage of ideas, and putting these together with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions to the fancy. Addison limited this definition considerably, by observing, that every resemblance of ideas does not constitute wit, but those only which produce delight and surprise. Pope defined wit to be a quick conception and an easy delivery; while, according to a more recent writer, it consists in an assimilation of distant ideas.

The word *wit* originally signified *wisdom.* A *witte* was anciently a *wise man;* the *wittenagemot,* or Saxon parliament, an assemblage of wise men. So late as the reign of Elizabeth, a man of pregnant *wit,* of great *wit,* was a man of vast *judgment.* We still say, *in his wits, out of his wits,* for in or out of sound mind. The word however is now applied in a more limited sense.

Without attempting to expose the insufficiency of the definitions above mentioned, or hazarding a new definition of our own, we shall endeavour to point out the varieties or different sorts of wit.

It is evident that wit excites in the mind an agreeable surprise, and that this is owing entirely to the strange assemblage of related ideas presented to the mind. This end is effected, 1. by debasing things pompous or *seemingly* grave; 2. by aggrandizing things little or frivolous; 3. by setting ordinary objects in a particular and uncommon point of view, by means not only remote, but apparently contrary. Of so much consequence are surprise and novelty, that nothing is more tasteless, and sometimes disgusting, than a joke that has become stale by frequent repetition. For the same reason, even a pun or happy illusion will appear excellent when thrown out extempore in conversation, which would be deemed execrable in print. In like manner, a witty repartee is infinitely more pleasing than a witty attack; for though in both cases the thing may be equally new to the reader or hearer, the effect on him is greatly injured, when there is access to suppose that it may be the slow production of study and premeditation. This however holds most with regard to the inferior tribes of witticism, of which their readiness is the best recommendation. We shall illustrate these observations by subjoining a specimen or two of each of these sorts of wit.

Of the first sort, which consists in the debasement of things great and eminent, Butler, amongst a thousand other instances, has given us those which follow.

> And now had Phœbus in the lap
> Of Thetis taken out his nap;
> And, like a lobster boil'd, the morn
> From black to red began to turn.
> Butler's *Hudibras,* part ii. canto ii.

Here the low allegorical style of the first couplet, and the simile used in the second, afford us a just notion of this lowest species, which is distinguished by the name of the *ludicrous.* Another specimen from the same author we have in these lines:

> Great on the bench, great in the saddle,
> That could as well bind o'er as swaddle,
> Mighty he was at both of these,
> And styl'd of *war,* as well as *peace:*
> So some rats of amphibious nature,
> Are either for the *land* or *water.*
> *Ibid.* part i. canto i.

In this coarse kind of drollery, those laughable translations or paraphrases of heroic and other serious poems, in which the authors are said to be travestied, chiefly abound.

The second kind, consisting in the aggrandisement of little things, which is by far the most splendid, and displays a soaring imagination, these lines of Pope will serve to illustrate:

> As Berecynthia, while her offspring vie
> In homage to the mother of the sky,
> Surveys around her in the blest abode,
> An hundred sons, and every son a god:
> Not with less glory, mighty Dulness crown'd,
> Shall take thro' Grubstreet her triumphant round;
> And her Parnassus glancing o'er at once,
> Behold a hundred sons, and each a dunce.

This whole similitude is spirited. The parent of the celestials is contrasted by the daughter of night and chaos; heaven by Grubstreet; gods by dunces. Besides, the parody it contains on a beautiful passage in Virgil adds a particular lustre to it. This species we may term *thrasonical,* or *the mock majestic.* It affects the most pompous language and sonorous phraseology, as much as the other affects the reverse, the vilest and most grovelling dialect.

To this class also we must refer the application of grave reflections to mere trifles. For that *great* and *serious* are naturally associated by the mind, and likewise little and trifling, is sufficiently evinced by the common modes of expression on these subjects used in every tongue. An apposite instance of such an application we have from Philips.

> My galligaskins, that have long withstood
> The winter's fury and encroaching frosts,
> By time subdued, (*what will not time subdue?*)
> An horrid chasm disclose.
> *Splendid Shilling.*

Of the third species of wit, which is by far the most multifarious, and which results from what may be called the queerness or singularity of the imagery, we shall give a few specimens that will serve to mark some of its principal varieties. To illustrate all would be impossible. The first shall be where there is an apparent contrariety in the things exhibited in connection. This kind of contrast we have in these lines of Garth:

> Then Hydrops next appears amongst the throng;
> Bloated and big she slowly sails along:
> But like a miser in excess she's poor,
> And pines for thirst amidst her wat'ry store.
> *Dispensary.*

A second sort is, where the things compared are what with dialecticians would come under the denomination of *disparates,* being such as can be ranked under no common genus. Of this we shall subjoin an example from Young.

> Health chiefly keeps an Atheist in the dark;
> A fever argues better than a Clarke:
> Let but the logic in his pulse decay,
> The Grecian he'll renounce, and learn to pray.
> *Universal Passion.*

A third variety in this species springs from confounding artfully the proper and the metaphorical sense of an expression. In this way, one will assign as a motive what is discovered to be perfectly absurd when but ever so little attended to; and yet, from the ordinary meaning of the words, has a specious appearance on a single glance. Of this kind we have an instance in the subsequent lines.

> While thus the lady talk'd, the knight
> Turn'd th' outside of his eyes to white,
> As men of inward light are wont
> To turn their optics in upon't.
> *Hudibras,* part iii. canto i.

A fourth variety, much resembling the former, is when the argument or comparison (for all argument is a kind of comparison) is founded on the supposal of corporeal or personal attributes in what is strictly not susceptible of them, as in the following passage.

> But Hudibras gave him a twitch
> As quick as lightning in the breech,
> Just in the place where honour's lodg'd,
> As wise philosophers have judg'd;
> Because a kick in that place more
> Hurts honour than deep wounds before.
> *Ibid.* part ii. canto iii.

The fifth and only other variety which we shall mention, is that which arises from a relation, not in the things signified, but in the signs, of all relations no doubt the slightest. Identity here gives rise to puns and clinches; resemplace to quibbles, cranks, and rhimes. Of these it is quite unnecessary to exhibit specimens.

WITCHCRAFT, a supernatural power of which persons were formerly supposed to obtain the possession by entering into a compact with the devil. They gave themselves up to him body and soul; and he engaged that they should want for nothing, and that he would avenge them upon all their enemies. As soon as the bargain was concluded, the devil delivered to the witch an imp, or familiar spirit, to be ready at a call, and do whatever it was directed. By the assistance of this imp and the devil together, the witch, who was almost always an old woman, was enabled to transport herself in the air on a broomstick or a spit to distant places to attend the meetings of the witches. At these meetings the devil always presided. They were also enabled to transform themselves into various shapes, particularly to assume the forms of cats and hares, in which they most delighted; to inflict diseases on whomsoever they thought proper, and to punish their enemies in a variety of ways.

The belief that certain persons were endowed with supernatural power, and that they were assisted by invisible spirits, is very ancient. The *sagæ* of the Romans seem rather to have been sorcerers than witches; and indeed the idea of a witch, as above described, could not have been prevalent till after the propagation of Christianity, as the heathens had no knowledge of the Christian *devil.* Witchcraft was universally believed in Europe till the sixteenth century, and even maintained its ground with tolerable firmness till the middle of the seventeenth. Vast numbers of reputed witches were convicted and condemned to be burnt every year. The methods of discovering them were various. One was, to weigh the supposed criminal against the church Bible, which, if she was guilty, would preponderate: another, by making her attempt to say the Lord's Prayer. This no witch was able to repeat entirely, but would omit some part or sentence of it. It is remarkable, that all witches did not hesitate at the same place, some leaving out one part, and some another. Teats, through which the imps sucked, were indubitable marks of a witch: these were always raw, and also insensible, and if squeezed, sometimes yielded a drop of blood. A witch could not weep more than three tears, and that only out of the left eye. This want of tears was, by the witch-finders, and even by some judges, considered as a very substantial proof of guilt. Swimming a witch was another kind of popular ordeal generally practised. For this she was stripped naked, and cross-bound, the right thumb to the left toe, and the left thumb to the right toe. Thus prepared, she was thrown into a pond or river, in which, if guilty, she could not sink; for having, by her compact with the devil, renounced the benefit of the water of baptism, that element, in its turn, renounced her, and refused to receive her into its bosom. Sir Robert Filmer mentions two others by fire: the first, by burning the thatch of the house of the suspected witch; the other, burning any animal supposed to be bewitched by her, as a hog or ox. These, it was held, would force a witch to confess. The trial by the stool was another method used for the discovery of witches. It was thus managed: having taken the suspected witch, she was placed in the middle of a room upon a stool or table, cross-legged, or in some other uneasy posture; to which, if she submitted not, she was then bound with cords; there she was watched, and kept without meat or sleep for the space of twenty-four hours; for, they said, within that time they should see her imp come and suck. A little hole was likewise made in the door for imps to come in at; and lest it should come in some less discernible shape, they that watched were taught to be ever and anon sweeping the room, and if they saw any spiders or flies, to kill them: if they could not kill them, then they might be sure they were imps. If witches, under examination or torture, would not confess, all their apparel was changed, and every hair of their body shaven off with a sharp razor, lest they should secrete magical charms to prevent their confessing. Witches were most apt to confess on Friday. By such trials as these, and by the accusation of children, old women, and fools, were thousands of unhappy women condemned for witchcraft, and burnt at the stake.

For a considerable time after the inquisition was erected, the trials of witches, as heretics, were confined to that tribunal; but the goods of those who were condemned being confiscated to the holy office, its ministers were so active in discovering sorcerers, that the different governments found it necessary to deprive them of the cognizance of this crime. On the continent, commissioners were then appointed for the discovery and conviction of witches, who, though less active than the inquisitors, were but too zealous in prosecuting their function. In 1494, Sprenger and Institor, two persons employed in this commission, published a collection of trials, most of which had come before themselves, under the title of *Malleus Maleficarum.* This served as a kind of institute for their successors.

The first writers against witchcraft were stigmatized as atheists, though they only endeavoured to prove the imbecility of the persons accused, and the infatuation or the knavery of their accusers. Such were the epithets bestowed by Dr More. Wierus, the disciple of the celebrated Agrippa, gave rise to the first great controversy on this subject. His master had taught him humanity; and he endeavoured, but with too feeble a hand, to stop the bloody proceedings of the judges. Wierus appears to have been a well-disposed, weak man, with extensive reading on this subject, but too narrow-minded to comprehend it thoroughly. He involved himself in unspeakable difficulties, by admitting the action of supernatural powers in certain diseases, and in possessions, while he denied that witches had any concurrence in them. These appearances, said he, are illusions of the devil, who persuades simple and melancholy persons that the mischief he himself performs is done by them, and at their pleasure. He was weak enough to attempt the explanation of every story alleged by his antagonists, without questioning the truth of the facts.

Bodin, a French lawyer of eminence, who had assisted at several trials of witches, wrote against Wierus, in his *Demonomania.* He urged the concurrent testimonies of sufficient witnesses, and the confessions of the witches themselves, to establish the existence of sorcery. Wierus owned that the unhappy persons believed themselves to be guilty of the crimes alleged against them, but that they were deceived by the devil. But what do you make of the witches' meetings, cried Bodin? The witches, replied his antagonist, are atrabilious. This explanation was so unsatisfactory, that Wierus passed for a magician, whom the devil had furnished with specious arguments to save others from punishment. Lerchemer, Godelmann, Ewichius, Ewaldus, and some others, followed him, notwithstanding this stigma; but they were opposed by men of more acuteness and consistency than themselves; by Remigius, who had condemned several hundreds of sorcerers to the flames; Delrio, whose book is a complete Corpus Magiæ; Cujacius, Erastus, Scribonius, Camerarius, and a crowd of others.

In this country, while the belief in witchcraft was supported by royal authority (for James I. is universally known to have written on demonology), countenanced by Bacon, and generally adopted among the people, only one writer was hardy enough to oppose it. This was Reginald Scot, who published a collection of impostures detected, under the title of "Discoveries of Witchcraft." James ordered the book to be burnt by the common executioner, and the judges continued to burn witches as usual. During the civil wars, upwards of eighty were hanged in Suffolk, on the accusations of Hopkins the witch-finder. Webster was the next writer against witchcraft, but he had a different fate from that of Scot, for most of his arguments were refuted by Glanville. This very acute writer was induced to publish his Philosophical Considerations about Witchcraft, by the apprehension that the increasing disbelief of witches and apparitions tended to affect the evidences of religion, and even of a Deity. In respect of argument he was certainly superior to his adversaries; his reasoning is perspicuous, though sometimes subtile, placed on the most specious foundations of evidence, and arranged with great skill.

On the continent, this controversy seemed almost forgotten, till Bekker published his *Monde Enchantée*, in which he denied the existence of witches, on the Cartesian principle that the Deity is the source of all action, consequently actions so opposite to his nature and attributes cannot be supposed to exist. He was answered by Frederick Hoffmann, the father of the modern theory and practice of medicine, in his dissertation *De Diaboli Potentia in Corpora.*

The latest witchcraft phrensy was in New England about the year 1692, when the execution of witches became a calamity more dreadful than the sword or the pestilence. The accusers became so daring, that neither civil nor religious authority would have proved a security against their attacks, if all the prosecutions had not been suddenly dropped, and the prisoners set at liberty. So far did those wretches proceed in absurdity, that a dog was accused of throwing persons into fits by looking at them. As soon as the prosecutions were stopped, all reports of witchcraft ceased.

It would be ridiculous to attempt a serious refutation of the existence of witches; and the task has long been unnecessary. In this country, at least, the discouragement long given to all suspicion of witchcraft, and the repeal of the statutes against that crime, have very much weakened, though perhaps they have not entirely eradicated, the persuasion. On the continent, too, it is evidently on the decline; and notwithstanding the exertions of Dr de Haen, and of the celebrated Lavater, we have little doubt that in a short time posterity will everywhere wonder at the credulity of their ancestors. That there ever were witches, is an opinion which cannot for a moment be admitted by a thinking man. The actions imputed to them were either absurd or impossible; the witnesses by whose evidence they were condemned, either weak enthusiasts or downright villains; and the confessions ascribed to the witches themselves, effects of a disordered imagination produced by cruel treatment and excessive watchings. As to the nightly meetings, demonologists themselves have been obliged to confess that they were nothing else but uneasy dreams, often produced by soporific compositions. The facts which have been brought forward by the advocates for witchcraft bear in their front the most evident marks of trick and imposture; and this has constantly been detected whenever these facts have been properly examined.

WITEBSK, a government or stadtholderate of the Russian dominions in Europe, formerly a portion of what was denominated White Russia, but now bearing the name of the largest city within it. It extends in north latitude from 54° 42′ to 57° 21′, and in east longitude from 15° 35′ to 21° 39′. It is bounded on the north-west by Livonia, on the north and north-east by Pfkow, on the east by Smolensko, on the south-east by Mohilew, on the south-west by Minsk, and on the west by Wilna and Courland. It is divided into twelve circles, with a capital to each; besides which there are twenty-three other cities or towns, and 12,185 villages. It is 14,690 square miles in extent, and contains 934,900 inhabitants.

The whole is a level plain, without hills; and even hillocks are rare, so that nothing is to be seen but sandy fields, with here and there the banks of the rivers, and occasionally a few small lakes. The soil is poor, of sand or sandy loam, with a thin covering of vegetable mould. The chief river is the Duna, which receives and carries to the sea the waters of the Mesha, the Kasplia, the Ula, the Polota, the Drissa, the Druja, the Saryja, the Feananka, and the Ewest. Among the lakes, the most extensive are the Usmyn, the Usmiat, the Osweja, and the Lubahu, which last indeed belongs in part to Livonia.

The greater part of the inhabitants adhere to the Catholic church, or to the Greek united. The former has an archbishop at Mohilew, with sixty-three parishes and forty monasteries; the second has a bishop at Polozk, with 135 parishes and thirty-three monasteries. The orthodox Greeks have sixty-five parishes. Among the Lithuanians, the Livonians, and the Germans, the Protestants are the most numerous. The Jews are numerous, but chiefly in the cities and towns.

The capital of this government, the city of the same name, and the capital of a circle, stands on the river Duna or Dwina, 460 miles from St Petersburg. It is surrounded with old walls and towers, has narrow and crooked streets, and contains three Catholic and eleven Greek churches, 1940 houses, and about 14,500 inhabitants. It has six Greek and two Catholic monasteries, and three synagogues for the Jews. The city has a considerable number of tanneries, the leather made at which is sent partly to Riga and partly to St Petersburg. It has several large fairs, where much business is transacted. Long. 29. 55. E. Lat. 55. 11. N.

WITENA MOT, or WITENA *Gemot*, among the Anglo-Saxons, was a term which literally signified the assembly of the wise men; and was applied to the great council of the nation, afterwards called the *parliament*.

WITHERS OF A HORSE, the juncture of the shoulder-bones at the bottom of the neck and mane, towards the upper part of the shoulder.

WITNESS, in *Law*, a person who gives evidence in any cause, and is sworn to speak the truth.

WITNEY, a market-town and parish of the county of Oxford, in the hundred of Bampton, sixty-nine miles from London and eleven from Oxford. It stands on the river Windrush. It consists of two streets, at the end of one of which is a fine church in the Gothic style. There is also an endowed grammar-school, with a good library. This place has long been celebrated for the manufacture of blankets, which is still carried on extensively, and they still maintain their character for superior warmth and lightness. There is a market on Thursday. The population of this town amounted in 1821 to 2827, and in 1831 to 3190; but the whole parish, comprehending also four hamlets, in 1831 had 5336 inhabitants.

WITSIUS, HERMAN, a learned divine, was born on the 12th of February 1636, at Enckhuysen in North Holland. His father, a member of the municipal council of that place, was the author of some pious meditations, written in his native tongue. In 1650 he became a student in the university of Utrecht, where he distinguished himself by his rapid progress in different branches of learning. At the age of eighteen, he publicly recited a Hebrew discourse on the Messiah of the Jews and the Christians. He afterwards removed to Groningen, in order to attend the lectures of Desmarets. He was ordained a minister in 1657, and exercised his functions in different places till 1675, when he was appointed professor of divinity at Franeker. In 1680 he was nominated to a similar chair at Utrecht; and in 1685 he proceeded to London as chaplain of the Dutch embassy sent to congratulate the king on his accession to the throne. In 1698 he succeeded Spanheim as professor of divinity at Leyden; but this office he afterwards exchanged for the rectorship of the Theological College. He died on the 22d of October 1708, in the seventy-third year of his age.

Witsius was a judicious, as well as a learned and pious writer; and some of his works continue to be held in much estimation. Of his more important publications we subjoin a notice. 1. Judæus Christianizans circa Principia Fidei et SS. Trinitatem: sive, Dissertatio de Principiis Fidei Judæorum, &c. Traj. ad Rhen. 1661, 12mo. 2. De Œconomia Fœderum Dei cum Hominibus libri iv. Leovard. 1677, 8vo. This treatise has frequently been printed. It was translated into English, and in that form has likewise passed through many editions. In Hervey's Theron and Aspasia, it receives very high commendation. "The Œconomy of the Covenants is a body of divinity, in its method so well digested, in its doctrine so truly evangelical, and, what is not very usual with our systematic writers, in its language so refined and elegant, in its manner so affectionate and animating, that I would recommend it to every student of divinity." 3. Diatribe de septem Epistolarum Apocalypticarum Sensu historico ac prophetico. Franeq. 1678, 12mo. 4. Exercitationes Sacræ in Symbolum quod Apostolorum dicitur; et in Orationem Dominicam. Franeq. 1681, 4to. 5. Ægyptiaca et Δεκάφυλον: sive, de Ægyptiorum Sacrorum cum Hebraicis Collatione libri tres; et de decem Tribubus Israelis liber singularis. Accessit Diatribe de Legione Fulminatrice Christianorum sub imperatore M. Aurelio Antonino. Amst. 1683, 4to. In this valuable work, Witsius maintains, against Sir John Marsham and Dr Spencer, that the Jews did not borrow from the Egyptians any part of their religious rites and ceremonies. The Ægyptiaca are reprinted in the great collection of Ugolini, *Thesaurus Antiquitatum Sacrarum*, tom. i. The dissertation on the thundering legion was attacked by Larroque. 6. Miscellanea Sacra. Traj. ad Rhen. 1692–1700, 2 tom. 4to. The first volume, including thirty additional dissertations, was reprinted at Leyden in 1695. 7. Exercitationum Academicarum, maxima ex parte historico-critico-theologicarum, decas. Traj. ad Rhen. 1694, 12mo. 8. Meletemata Leidensia. Lugd. Bat. 1703, 4to. A collective edition of his works appeared at Herborn, 1712–7, 6 tom. 4to. Besides his Latin treatises, he published several practical works in Dutch. He was the editor of a Latin version of Godwin's Moses and Aaron, printed at Utrecht in 1690, and of Gataker's *Opera Critica*, printed at the same place in 1698. (x.)

WITT, John de, a celebrated Dutch statesman, was the son of Jacob de Witt, burgomaster of Dort, and was born in 1625. He became well skilled in the civil law, politics, mathematics, and other sciences, and wrote a treatise on the Elements of Curved Lines, published by Francis Schooten. Having taken his degree of doctor of laws, he travelled into foreign courts, where he became esteemed for his genius and prudence. At his return to his native country in 1650, he became pensionary of Dort, then counsellor-pensionary of Holland and West Friesland, intendant and register of the fiefs, and keeper of the great seal. He was thus at the head of affairs in Holland; but his opposition to the re-establishment of the office of stadtholder, which he thought a violation of the freedom and independence of the republic, cost him his life when the prince of Orange's party prevailed. He and his brother Cornelius were assassinated by the populace at the Hague in 1674. He was only forty-seven years of age.

WITTENBERG, a circle of the Prussian province of Saxony, and of the government of Merseburg, extending over 330 square miles, and comprehending five cities and towns, 104 villages, and 28,700 inhabitants. The capital is the city of the same name on the river Elbe, over which is a wooden bridge of about 1000 feet in length. It is a place endeared to the Protestants of Germany, as the cradle of the reformed religion, where Luther first preached, and where he and Melanchthon were buried. It now contains five churches, 320 houses, and 6500 inhabitants, including the military and their families. The university has been removed, but the city still retains an ecclesiastical seminary. Wittenberg has suffered from the hostilities of 1813 and 1814. There is but little commerce, although some linen and woollen cloths are made, and there are several distilleries and breweries. Long. 12. 39. 39. E. Lat. 51. 52. 45. N.

WIVELSCOMBE, a market-town of the county of Somerset, in the hundred of West Kingsbury, ten miles from Taunton and 156 from London. It stands on the river Tone. It formerly had considerable manufactories of coarse woollen goods, which have nearly disappeared by the rivalry of the northern counties. The town has a corporation, and is governed by a portreeve. It has a good market on Tuesday, and two annual fairs. The population amounted in 1821 to 2791, and in 1831 to 3047.

WIVENHOE, a small town of the county of Essex, in the hundred of Lexden, fifty-four miles from London. It stands on the navigable river Colne, and is the place where the Colchester oysters are shipped for the London market. It has a regular custom-house and convenient quay. The population amounted in 1821 to 1287, and in 1831 to 1714.

WLADIMIR, a province or stadtholderate in the central part of the Russian dominions in Europe. It extends in north latitude from 54° 58′ to 57° 11′, and in east longitude from 37° 32′ to 43° 11′. It is bounded on the north-west by Twer, on the north by Jaroslaw, on the north-east by Kostroma, on the east by Nishegorod, on the south by Riazan, and on the west by Moscow. It is divided into thirteen circles, and comprehends thirteen cities and 4828 villages, included in 1062 parishes. The extent is 19,338 square miles, and the population is 1,334,500 persons. They are mostly of the original Russian race, and such adhere to the Greek church; but there are some Poles and Germans, and a few Tartars. The greater part of the peasantry is in a state of slavery. Of these upwards of 300,000 belong to the nobility, and about 150,000 to the emperor.

The whole is a level district, with no elevation reaching to 500 feet above the level of the sea. It has much wood, much heath land, and many morasses. The sloping of the land is towards the Wolga, which does not touch the province, but receives the waters of its several streams. The chief of these rivers is the Oka, into which the Kliasma, that comes from Moscow, and the other streams, pour their waters. There are many lakes: the largest of them is the Plestsckeiwo, which is about five miles across, and is the means of communication between the city of Moscow and the Wolga. Peter the Great was induced to form upon it an institution for building vessels. The climate of Wladimir is severely cold in winter and intensely hot in summer, exceeding in both temperatures that of the adjoining province of Moscow. The rivers are generally closed by ice in the beginning of November, and do not open again till towards the end of March. Sharp night-frosts are common even in May. The chief pursuit is agriculture, but it is very slightly productive. Much of the land is clay mixed with stones, and often requires six horses to plough it, and then the product is scarcely more than three times as much as the seed that is sown. The only kinds of grain are winter rye, barley, and oats, and a small portion of summer wheat; but the whole of these do not yield, in the average of years, more than sufficient for the consumption of ten months, and supplies are obtained from the neighbouring provinces. Hemp and flax are more important products of the soil, and are extensively cultivated. The forests yield timber, potashes, and pitch. The breeding of cattle is considerable. The horses in this province are much valued, and great pains have been taken by the government to improve the breed of them.

There are some iron mines, which yield not more than from fifty to sixty quintals of iron in bars. The manufactures are, woollen cloths, several kinds of linen, and some cotton goods, a considerable quantity of glass-ware, some paper and soap, all of which are sent by land to Moscow. The capital is the city of the same name, 602 miles from St Petersburg. It is very ancient, and, from 1157 to 1328, was the capital of the empire; but it has vastly declined from its former greatness, nor are many traces of that greatness now to be seen, except the two cathedral churches of St Mary and Dmitriew. It is now a place of little trade; and though, besides the cathedrals, it contains twenty-five churches, there are not more than 1600 inhabitants. It is the capital of a circle of its name. Long. 40. 22. E. Lat. 56. 17. N.

WLODZIMIRZ, a circle of the Russian government of Volhynia. It extends in north latitude from 50° 22′ to 50° 57′, and in east longitude from 24° 8′ to 24° 58′. The river Bug drains it, and forms the boundary towards Poland. The soil is good, and yields abundant crops of wheat, rye, barley, pease, flax, hops, and tobacco. The woods and meadows are extensive and profitable. The capital is the city of the same name on the river Lug. It contains several Greek and Catholic churches, with Jewish synagogues, a monastery, 540 houses, and 3400 inhabitants, mostly Jews. It is 1070 miles from St Petersburg. Long. 24. 15. E. Lat. 50. 44. 30. N.

WOAHOO, one of the Sandwich Islands, containing, as near as can be conjectured, 60,000 inhabitants. Long. of the anchoring place, 202. 9. E. Lat. 21. 43. N.

WOBURN, a market-town of the county of Bedford, in the hundred of Manshead, forty-two miles from London. It has a market on Friday. It is tolerably well built, but the most prominent object is the magnificent seat of the duke of Bedford, erected on the site of the ancient abbey. Its façade, the interior richly ornamented with pictures and statues, the splendid and appropriate furniture, with the extensive and picturesque park, and the beautiful gardens, attract numerous visitors. The population of the town amounted in 1821 to 1656, and in 1831 to 1827.

WODEVILLE, Anthony, earl of Rivers, brother to the queen of Edward IV., was born in the end of 1442, or in the beginning of 1443. Though one of the most accomplished men of his age, very little is known of his private history. He was early and constantly employed either in the tumults of those turbulent times, or in discharging the duties of some of the highest offices of the state, with which he was invested. Yet he found leisure to cultivate letters, and to be the author of works which, though of little value now, made some noise in that age, when learning was at a low ebb in England. These consisted chiefly of translations from the French; and his lordship, and his printer Caxton, were the first English writers who had the pleasure to see their works published from the press. This accomplished, brave, and amiable nobleman was treacherously imprisoned by Richard III. in Pontefract Castle, where, during his confinement, he composed a short poem, which has been preserved by John Rous of Warwick, and breathes, says Dr Henry, a noble spirit of pious resignation to his approaching fate. He was beheaded on the 23d of June 1483, in the forty-first year of his age.

WODROW, Robert, a well-known ecclesiastical historian, was born at Glasgow in the year 1679. His father, James Wodrow, a man of piety and learning, had been licensed to preach in 1673; but during the times of persecution he obtained no settled charge, and was obliged to live a considerable time under concealment, occasionally preaching to the proscribed presbyterians in the west of Scotland. After the Revolution, he became one of the ministers of Glasgow; but resigned his pastoral charge in 1692, on being elected professor of divinity in that university. Robert, his second son, entered the university in 1691; and after passing through the usual academical course, with the view of qualifying himself for the sacred ministry, he became a student of divinity under his father. About the same time (in 1698) he was chosen librarian to the university; an office which he held for four years, availing himself of the opportunities it afforded for carrying on his literary and antiquarian pursuits, and also for becoming acquainted with many persons of eminence, with whom, in after life, he maintained a regular correspondence. On leaving the university, he resided for a short time in the family of Sir John Maxwell of Nether Pollock, one of the senators of the College of Justice; and having offered himself as a probationer to the presbytery of Paisley, he was licensed to preach the gospel in March 1703. In the summer following, the parish of Eastwood, where Sir John Maxwell resided, became vacant by the death of the Rev. Matthew Crawford, the author of a history of the Church of Scotland (a work of some value, which still remains unpublished); and Wodrow having received an unanimous call from the heritors, elders, and congregation, to supply the charge, he was ordained minister of that parish on the 28th of October 1703. As Eastwood was at the time one of the smallest parishes in the west of Scotland, he was the better enabled to devote his leisure hours to the prosecution of his favourite pursuits, which then included natural history as well as antiquities. To Edward Lhuyd, the learned keeper of the Ashmolean Museum at Oxford, he writes in August 1790, "My lott is by providence cast in the parish of Eastwood, and my house within a quarter of a mile from the Aldhous-bourn, where you and I were a-lithoscoping. My pastorall charge does not allow me that time I once had to follow out these subterranean studyes, but my inclination is just the same as when I saw you, or rather greater; and I take it to be one of the best of diversions from more serious work, and in itself a great duty, to view and admire my Maker in his works as weel as his word. I have gott together some store of our fossiles hereabout from our marle, our limestone, &c., and heartily wish I had the knowing Mr Lhuyd here to pick out what he wants, and to help me to classe a great many species I know not what to make of."

Throughout the whole of his extensive correspondence, Wodrow evinces his inquisitive turn of mind, thirsting to acquire information on all subjects, whether as regarded science, literature, or the state of religion; and he often apologizes for his "Athenian disposition," or, as in one place he more quaintly terms it, "his Athenian or queristicall temper." Thus, soon after his settlement at Eastwood, we find him availing himself of his acquaintance with the Rev. Patrick Simpson of Renfrew, and other aged ministers, who had been ordained before the Restoration, to glean their recollections of the more eminent presbyterians who flourished during the period usually called the Second Reformation; and many of their memorials are treasured up in his MS. volumes of Analecta. These pursuits, however, never interfered with his parochial duties, and his success and faithfulness as a Christian minister endeared him to his own people, while his reputation as a preacher was considerable; yet, not being given to change, he resisted all attempts made to translate him to some more important field of labour in the church, to Glasgow in 1712, to Stirling in 1717, to the same place in 1726, and finally to Renfrew in 1729. He was regular in his attendance on the several ecclesiastical courts, and he availed himself of his periodical visits to Edinburgh during the meetings of the General Assembly to prosecute his historical researches. As might have been expected from a person of his habits, pursuits, and education, he took a lively interest in all ecclesiastical proceedings; and in questions involving matters either of sound doctrine, or of discipline and church government, he was invariably found on the popular side. Thus we find him a steady opponent to the imposition of the abjuration oath, hostile to the restoration of lay-patronage, and taking a decided though

Wodrow.

reluctant part in the well-known case of his father's successor, Professor Simson of Glasgow, who was finally deposed from his office for teaching erroneous doctrines. However much he might lament the exercise of the powers conferred by the obnoxious act alluded to, which was passed by the Jacobite party for the evident purpose of subverting the church as an establishment, he uniformly inculcated submission to the civil power in such matters, and used his best endeavours to promote peace and harmony in cases of disputed settlements. It might not indeed be possible to overestimate the amount of injury done to the interests of religion, and of the country at large, by this act of Queen Anne, restoring to lay-patrons the exercise of a civil right, in regard to the presentation of ministers to vacant parishes, without some efficient check on its due exercise. In his MS. correspondence we find Wodrow often expressing his deep-felt regrets at the evil effects it was then beginning to produce. "If the Lord open not a door of relief (so he writes in 1717), we are in the utmost hazard of a corrupt ministry." And the reiterated expression of his fears of "a corrupt ministry," and his remarks on "the servile crouching (of the probationer) to every thing his patron happens to be fond," were but too fully justified by the declining state of the church during the last century. Looking at its effects during Wodrow's own time, it was the primary cause of ejecting from the bosom of the church some of her most faithful ministers, of alienating the affections of the humbler classes of the people, who retained a longing after the fruits of gospel ministrations, and of fostering in those who continued within its pale a growing laxity of principle, however outwardly its standards were professed; and thus, while no adequate means were provided for the spiritual wants of an increasing population, and no attempts made to win back to the fold the people who had left it in search of more faithful and devoted pastors, the church as an establishment seemed fast verging into a state of languor and spiritual death. But it would be out of place to enlarge on such a topic, even if Wodrow had filled a more conspicuous situation in the church. His reputation is founded on his literary labours as a diligent and successful investigator of the history of the church prior to his own times.

The work by which Mr Wodrow is best known, is "The History of the Sufferings of the Church of Scotland from the Restoration to the Revolution." Edinb. 1721-2, 2 vols. folio. It was the labour of many years. In 1717, having prepared the first portion of it, the manuscript was submitted to George Ridpath and other literary friends, and he profited by their suggestions. Two years later, the plan was laid before the General Assembly, when it was cordially approved of, and an act was passed recommending the members of Assembly and the several ministers of the church to subscribe for copies, and "to deal" with such in their bounds as were well disposed to encourage the work, "now ready for the press." He obtained by those means a most respectable list of subscribers; and on its publication, the work being dedicated to George the First, copies of it were presented, through Dr Fraser, to the king, the queen, the prince and princess of Wales, by all of whom it was most graciously received. In fact, the reception of the work by the public must have been gratifying to the author; and he appears from his correspondence to have received with comparative indifference some scurrilous attempts to depreciate his labours by the nonjuring episcopalians, or rather by one of their adherents, Alexander Bruce, advocate, first in an anonymous tract, "The Scottish Behemoth dissected, in a Letter to Mr Robert Wodrow, &c;" Edin. 1722, folio; and then in the preface to a Life of Archbishop Sharpe, 1723, 8vo. Mr Bruce next announced, in 1724, a great work, an "Impartial History of the Affairs in Church and State in Scotland from the Reformation to the Revolution," in two volumes folio. He did not survive long enough to make much progress in this work, which was taken up by Bishop Keith, who published only the first volume in 1734, bringing the history down to the year 1568. Keith's history is only important as a collection of materials, for the author was equally destitute of acuteness and liberality. To what extent he may have profited by Bruce's labours, is nowhere stated.

It does not appear in what manner Wodrow's History was again brought under the notice of George the First; but his majesty, "to certify our esteem of the said author and his works, by bestowing on him some mark of our bounty," ordered the sum of one hundred guineas to be paid to the Rev. Robert Wodrow by the Treasury. This grant is dated the 26th of April 1725; and such a mark of royal favour, wholly unexpected on Wodrow's part, was well bestowed on one whose labours served by contrast to exhibit in lively colours the advantages which were secured to Great Britain by the Hanoverian succession. In more recent times public attention was directed to the work by the high eulogium of Mr Fox on its fidelity and impartiality; and the demand having increased its price beyond the means of ordinary purchasers, a new edition in a more commodious form was published at Glasgow in 1830, 4 vols. 8vo, with a memoir of the author prefixed, by Robert Burns, D. D., one of the ministers of Paisley. The work itself was seasonably undertaken, the materials were ample, and in general not difficult of access; the events were still recent, and many of those who had experienced the hardships and sufferings of the times were either still alive or had been personal friends of the author; and he brought to the task a singular degree of industry, and a fidelity and impartiality which compensated for his want of literary skill and elegance of composition; and by incorporating such a mass of original and authentic documents, he has rendered his work interesting by the copiousness and minuteness of its details, no less than by exhibiting an appalling picture of the times.

The publication of this great work had no effect in relaxing Wodrow's literary ardour. It had always been with him a cherished plan to form a series of biographical memoirs of the more eminent ministers in the church of Scotland; and he took every opportunity of collecting materials for that design. Before proceeding with this task, he wrote a memoir of his father, Professor Wodrow, who was well entitled by his learning and usefulness to such a mark of filial affection and regard. He commences this memoir with the following remark: "When I have a design of making all the collections I can now recover, concerning the lives of persons in this church and nation, remarkable for piety and usefulness, the apostolical rule of shewing first piety at home, and requiting parents, seems to lead me to begin with my worthy and excellent father." It is dated February 5th, 1724, and the MS. remained in the possession of the family for more than a century. This "Life of James Wodrow, A. M., Professor of Divinity in the University of Glasgow," was published at Edinburgh in 1828, under the direction of the late Dr John Campbell, one of the ministers of that city. The series of lives, chiefly compiled between 1726 and 1733, forms ten volumes in folio, with four quarto volumes of appendix. These volumes are preserved in the library of the University of Glasgow; and a selection was commenced in 1834 for the members of the Maitland Club, under the title of "Collections upon the Lives of the Reformers and most eminent Ministers of the Church of Scotland." This work is certainly not the most important of Wodrow's labours. The lives are compiled and filled with extracts from works now much better known and more accessible than in his days, and being in most instances only first draughts hastily put together, the style is remarkably careless and slovenly. The lives already printed, however, are rendered of much greater value by the copious illustrations of the editor, Mr

W. J. Duncan, whose researches have been most assiduous and successful.

Wodrow's studious habits appear to have injured his health; and during the latter years of his life his usual pursuits were often interrupted by sickness, and he at length sunk under a gradual decline on the 21st of March 1734, in the 55th year of his age. In the year 1708 he was married to Margaret, daughter of Patrick Warner, minister of Irvine, and grand-daughter of William Guthrie, minister of Fenwick, author of a well-known practical treatise, "The Trial of a saving Interest in Christ." Of a family of sixteen children, nine, with their mother, survived him. His last illness he bore with much Christian fortitude and faith in the gospel, thus giving "a testimony in his practical experience to the efficacy of those holy truths which he preached so faithfully, and vindicated so nobly by his writings."

In the course of his researches Mr Wodrow had industriously formed an extensive and important collection of manuscripts, chiefly relating to ecclesiastical affairs in Scotland. Some years after his death, the collection was offered for sale by his family. In May 1742, a portion of the MSS. was purchased by direction of the General Assembly, and this portion now remains the property of the Church. Fifty years later (in 1792) the great mass of his other MSS. and printed tracts was sold to the Faculty of Advocates, with the exception of his Biographical Collections (already mentioned), which were obtained about the same time by the University of Glasgow. In June 1828, the Faculty of Advocates likewise secured, what cannot fail to be esteemed an important accession to the Wodrow Manuscripts, 1st, his "Analecta," in six volumes, closely written, being a kind of note-book or diary, in which he has preserved a valuable and amusing record of literary intelligence, as well as remarkable occurrences, and the news of the day; 2d, a collection of his own letters, in three volumes, closely written (the first volume not being discovered), from March 1709 to December 1731, comprising copies of nearly 600 letters, which are well worthy of publication; and, 3d, the regular series of Letters addressed to him by literary persons, or by friends and relations, arranged by himself in chronological order, in twenty-two volumes 4to, and containing upwards of 3880 letters, between the years 1694 and 1733. In mentioning these collections, it may be proper to add, that, for illustrating the literary and ecclesiastical history of the period which they embrace, the publication of no similar works would be of greater importance than that of Wodrow's Analecta, with an extensive but judicious selection from his Correspondence. (C. C. C.)

WODSTOCK, a market and borough town of the county of Oxford, in the hundred of Wootton, sixty-three miles from London. It stands on a small stream that falls into the Isis. It is pleasantly situated, and contains some good houses. There are two branches of manufacture, that of fine leather gloves, and of good steel cutlery and steel ornaments; but they are more celebrated for the finish of the work than for the extent of their productions. Wodstock returns one member to parliament. There is a good market on Tuesday. The magnificent palace of the duke of Marlborough adjoins the town. The building, the gardens, the park, with the pictures and statues that adorn it, are objects of great attraction; and the numerous visitors to it contribute in some degree to the prosperity of the town. The population in 1821 amounted to 1455, and in 1831 to 1380.

WOKINGHAM, a market-town of Berkshire, in the hundred of Sunning, thirty-two miles from London. It is within Windsor Forest, and the courts by which it is regulated are held here. It has a large market-place, which is well attended on Tuesday, an endowed school; and near it is an hospital, founded in 1663, for a master and six brethren under the direction of the company of the drapers in London. There is also a charity of L.50, to be paid to three maidens who have served the same master during three successive years. The population in 1821 amounted to 2490, and 1831 to 2692.

WOLEIN, a town of the Austrian province of Moravia, in the circle of Iglau. It contains 160 houses, with 1206 inhabitants, who are chiefly occupied in making woollen cloth.

WOLF, Christian, a celebrated German philosopher, was born at Breslau, on the 24th of January 1679. After having been well instructed in the rudiments of learning and science in his own country, Wolf prosecuted his studies successively in the universities of Jena and Leipzig. At the age of twenty-six he had acquired so much distinction that he was appointed professor of mathematics, and soon afterwards of philosophy in general, in the university of Halle. After Leibnitz had published his *Theodicé*, Wolf, struck with the novelty of the edifice which that philosopher had raised, assiduously laboured in the investigation of new metaphysical truths. He also digested the elements of mathematics in a new method, and attempted an improvement of the art of reasoning, in a treatise on the powers of the human understanding. Upon the foundation of Leibnitz's doctrine of monads, he formed a new system of cosmology and pneumatology, digested and demonstrated in a mathematical method. His work, entitled Thoughts on God, the World, and the Human Soul, was published in the year 1719; to which were added, in a subsequent edition, Heads of Ethics and Policy. Wolf was now rising towards the summit of philosophical reputation, when the opinion which he entertained on the doctrine of necessity being deemed by his colleagues inimical to religion, and an oration which he delivered in praise of the morality of the Chinese having given much offence, an accusation of heresy was publicly brought against him; and, though he attempted to justify himself in a treatise which he wrote on the subject of fatality, a royal mandate was issued in November 1723, requiring him to leave the Prussian dominions. Having been formerly invited by the landgrave of Hesse-Cassel to fill a professorship of mathematics and philosophy in the university of Marburg, Wolf now put himself under the patronage of that prince, who had the liberality to afford him a secure asylum. The question concerning the grounds of the censure which had been passed upon him was now everywhere freely canvassed; almost every German university was inflamed with disputes on the subject of liberty and necessity, and the names of Wolfians and Anti-Wolfians were everywhere heard. After an interval of nine years, the king of Prussia reversed his sentence of exile, and appointed him professor of the law of nature and of nations, and vice-chancellor of the university of Halle; where his return was welcomed with every expression of triumph. From this time he was employed in completing his institutes of philosophy, which he lived to accomplish in every branch except policy. In 1745 he was created a baron by the elector of Bavaria, and succeeded Ludwig in the office of chancellor of the university. He continued to enjoy these honours till the year 1754, when he expired on the 9th of April. He possessed a clear and methodical understanding, which, by long exercise in mathematical investigations, was particularly fitted for the employment of digesting the several branches of knowledge into regular systems; and his fertile powers of invention enabled him to enrich almost every field of science in which he laboured, with some valuable additions. The lucid order which appears in all his writings enables his readers to follow his conceptions with ease and certainty throughout the longest trains of reasoning. His works are partly in German and partly in Latin. His *Jus Naturæ*, published from 1740 to 1748, extends to no fewer than eight volumes in quarto, and must at least be considered as an adequate specimen of the author's perseverance.

Wolfenbuttel ‖ Wollaston.

WOLFE, James, was born at Westerham, in the county of Kent, about the beginning of the year 1726. His father was Lieutenant-general Edward Wolfe. He went into the army when very young, and applying himself with unwearied assiduity to the study of his profession, soon became remarkable for his knowledge and his genius. He distinguished himself at the battle of Lafelt when little more than twenty, and received the highest encomiums from the commander-in-chief. After the peace he still continued to cultivate the art of war. He contrived to introduce the greatest regularity and the exactest discipline into his corps, and at the same time to preserve the affection of every soldier. In 1758 he was present as a brigadier-general at the siege of Louisbourg. He landed first on the island at the head of a division; and in spite of the violence of the surf, and the force and well-directed fire of the enemy, drove them from their post with great precipitation. The surrender of the town, which happened soon after, was in a great measure owing to his activity, bravery, and skill. The fame which he acquired during this siege pointed him out to Mr Pitt, who was then minister, as the most proper person to command the army destined to attack Quebec. This was the most difficult and the most arduous undertaking of the whole war. Quebec was the capital of the French dominions in North America; it was well fortified, situated in the midst of a hostile country, and defended by an army of 20,000 men, regulars and militia, besides a considerable number of Indian allies. The troops selected for this expedition consisted of ten battalions, making up altogether about 7000 men. Such was the army destined to oppose three times their own number, defended by fortifications, in a country altogether unknown, and in a late season in that climate for military operations. But this little army, was always sanguine of success; for they were commanded by an officer who, by a very uncommon magnanimity and nobleness of behaviour, had attached the troops so much to his person, and inspired them with such resolution and steadiness in the execution of their duty, that nothing seemed too difficult for them to accomplish. The admirable skill with which his measures were planned, and the prudence and vigour with which they were executed, are well known. He landed his army on the northern shore of the river St Lawrence, in spite of the enemy, and forced them to a battle, in which they were completely defeated. The consequence of this battle was the reduction of Quebec and the conquest of Canada. In the beginning of the battle General Wolfe was wounded in the wrist by a musket-ball; he wrapt his handkerchief round it, continued to give his orders with his usual calmness and perspicuity, and informed the soldiers that the advanced parties on the front had his orders to retire, and that they need not be surprised when it happened. Towards the end of the battle he received a new wound in the breast; he immediately retired behind the rear rank, supported by a grenadier, and laid himself down on the ground. Soon after a shout was heard, and one of the officers who stood by him exclaimed, "See how they run!" The dying hero asked with some emotion, "Who run?" "The enemy," replied the officer; "they give way everywhere." The general then said, "Pray, do one of you run to Colonel Burton, and tell him to march Webb's regiment with all speed down to Charles river, to cut off the retreat of the fugitives from the bridge. Now, God be praised, I shall die happy!" He then turned on his side, closed his eyes, and expired.

The death of General Wolfe was a national loss universally lamented. He inherited from nature an animating fervour of sentiment, an intuitive perception, an extensive capacity, and a passion for glory, which stimulated him to acquire every species of military knowledge that study could comprehend, or that actual service could illustrate and confirm. This noble warmth of disposition seldom fails to call forth and unfold all the liberal virtues of the soul. Brave above all estimation of danger; generous, gentle, complacent, and humane, he was the pattern of the officer, the darling of the soldier. There was a sublimity in his genius which soared above the pitch of ordinary minds; and had his faculties been exercised to their full extent by opportunity and action, had his judgment been fully matured by age and experience, he would in all probability have rivalled in reputation the most celebrated captains of antiquity. His body was brought to England, and buried with military honours in Westminster Abbey, where a magnificent monument is erected to his memory.

WOLFENBUTTEL, a city of the duchy of Brunswick, in Germany. It is the capital of the province of the same name. It stands on the river Oker, and is surrounded with dilapidated walls. It was formerly the residence of the ruling family, but the palace is converted into a manufactory. There is a fine public library, with more than 200,000 volumes, in which is a statue of the poet Lessing, who was librarian. This city is the principal seat of the law courts. It has three Lutheran churches, 1100 houses, and 8300 inhabitants, who carry on fabrics of linen, silk, and leather, and some breweries and distilleries. Long. 10. 25. 49. E. Lat. 52. 8. 44. N.

WOLLAMAI Cape, the east point of Philip Island, on the south coast of New Holland. Long. 145. 25. E. Lat. 38. 38. S.

WOLLASTON, William, descended of an ancient family in Staffordshire, was born at Coton Clanford on the 26th of March 1659. His father was a private gentleman of small fortune. In 1674, the son was admitted a pensioner of Sidney College, Cambridge, where, notwithstanding several disadvantages, he acquired a great degree of reputation. In 1681, he commenced A. M., having previously been an unsuccessful candidate for a fellowship. In 1682, seeing no prospect of preferment, he became assistant to the head-master of Birmingham school. Some time after, he obtained a small lecture about two miles distant, but did the duty the whole Sunday; which, together with the business of a great free-school for about four years, began to break his constitution. During this space he likewise underwent a great deal of trouble and uneasiness, in order to extricate two of his brothers from some inconveniences to which their own imprudence had subjected them. In 1688 affairs took a new turn. He found himself, by a cousin's will, entitled to a very ample estate, and came to London that same year, where he settled, choosing a private, retired, and studious life. In 1722, he printed a few copies of his celebrated work, entitled "The Religion of Nature delineated." It was printed for sale in 1725, and so great was its success, that more than 10,000 were sold in a very few years. He had scarcely completed his treatise when he unfortunately broke his arm; and this accident adding strength to distempers that had been growing upon him for some time, accelerated his death, which happened upon the 29th of October 1724. He was a tender, humane, and in all respects worthy man, but is represented to have had something of the irascible in his constitution and temperament. His "Religion of Nature delineated" exposed him to some censure, as if he had disparaged Christianity by laying so much stress, as he does in this work, upon the obligations of truth, reason, and virtue, and by making no mention of revealed religion. But this censure must have been the offspring of ignorance or envy, since it appears from the introduction to his work that he intended to treat of revealed religion in a second part, which he lived not to finish.

WOLLASTON, William Hyde, was great-grandson of the preceding, and son of the Rev. Francis Wollaston, rector of Chiselhurst, and of St Vedast, Foster-lane, and precentor of St David's, who died in 1815. His father had seventeen children. William, his second son, was born on the 6th of August 1766, and received his academical education at Caius College, Cambridge, where he took his degree of M. D. in 1793.

He first settled as a medical practitioner at Bury St Edmund's; but meeting with little success, he removed to London, where however he was not more fortunate in his profession. The office of physician to St George's Hospital falling vacant, he was one of the candidates for the appointment; and on the election of his rival, Dr Pemberton, he was so much chagrined by his defeat, that he resolved to abandon the profession of medicine, and expressed his determination never again to write a prescription, were it even for his own father; and from this time his attention was wholly directed to natural science. Although almost every branch of science at different times engaged the attention of Dr Wollaston, chemistry was that to which he was most ardently devoted; and it is on his important discoveries in this department of natural philosophy that his reputation will chiefly rest. In pursuing his inquiries, he usually made his experiments on very small specimens of the substance which he wished to analyse. He possessed an uncommon neatness of hand, and invented the most ingenious methods of determining the properties and constituents of very minute quantities of matter. Among the delicate instruments which he was accustomed to make, was a sliding rule of chemical equivalents, and a galvanic battery of such small dimensions that it was contained in a thimble. He produced wire of platina so extremely fine as to be almost imperceptible to the naked eye. To him we are indebted for the discovery of the malleability of platinum, a discovery which is supposed to have yielded him above L.30,000; and he is likewise said to have derived great pecuniary advantages from several of his other discoveries and inventions, which, as they were generally of a practically useful nature, were calculated to produce a lucrative return.

Dr Wollaston was elected a fellow of the Royal Society in 1793, and second secretary on the 30th November 1806. His communications to the Philosophical Transactions were numerous and important. On the 30th November 1828, the Royal Society awarded to him one of the royal medals for his essay "On a method of rendering Platina malleable." Towards the end of 1828 he was seized with the disorder of which he died, and which was afterwards ascertained to be an effusion of blood in the ventricles of the brain. Feeling that his end was approaching, and being anxious that the knowledge of his discoveries and inventions should be preserved for the benefit of his fellow-creatures, he devoted his numbered hours, in the midst of pain and disease, to dictate such information as he thought worthy of being preserved.

At the time of his death, which occurred on the 22d December 1828, Dr Wollaston was senior fellow of Caius College. In February 1829, Dr Fitton, as president of the Geological Society, of which Dr Wollaston was for some time one of the vice-presidents, concluded his annual address with the following encomium on this eminent individual: "It would be difficult to name a man who so well combined the qualities of an English gentleman and a philosopher, or whose life better deserves the eulogium given by the first of our orators to one of our most distinguished public characters; for it was marked by a constant wish and endeavour to be useful to mankind."

WOLOGDA, one of those large divisions into which the European part of the Russian empire is formed, and commonly denominated a government or stadtholdership. The extent is given differently by several authors; but as Storch seems the preferable authority, it is here given according to his representation, at 151,074 square miles. It extends in north latitude from 58° 23′ to 64° 56′, and in east longitude from 38° 47′ to 57° 10′. It is bounded on the north by Archangel, on the north-east by Tobolsk, on the south-east by Perm and by Wiatka, on the south by Kostroma, on the south-west by Jaroslaw, on the west by Novogorod, and on the north-west by Olonetz.

The surface of this province is a most extensive plain, on the eastern side touching the Ural Mountains, a few branches or spurs from which penetrate into the north-east part. Besides these, no hills are to be seen, and but few elevations, but immeasurable woods, broad heaths and morasses, small lakes, and especially a most abundant supply of water in streams of all dimensions. The soil is of various qualities, clayey, loamy, and sandy, and in some parts there is good marl. There are however some tracts of good alluvial soil to be found over the worst subsoils. In most parts it is capable of cultivation, but the best portions are the south-west parts of the province. Cultivation in the whole province requires watchfulness with respect both to the weather, the nature of the soil, the rotation of crops, and the nature and quantity of manure; but, with the greatest attention to them, it is not common to obtain more than five times the quantity of the seed that is sown, even of rye, which is the most extensive crop; whereas in barley and oats not three times the seed are commonly obtained. Besides those kinds of grain, a little winter wheat is sown, and some pease. It is only in very good years that sufficient corn for the consumption is grown. According to Storch, the annual quantity of rye and wheat together does not exceed four English bushels for each person. Flax and hemp succeed better than either kind of grain. In some of the divisions beyond the Dwina, no other corn but barley is attempted to be raised. In the north-east part no fruit is grown; but in the south-west, in the gardens, apples and cherries come to a tolerable degree of ripeness. The cultivation of potatoes has of late years been introduced or extended, and affords a prospect of increasing the means of subsistence.

The manufacturing industry is not considerable, and only extends to common necessaries, such as woollen and linen goods, from their own sheep and flax. A little paper, some glass and earthenware, and a few metal articles, form the chief part of the products, exclusive of the leather, and of the brandy, which is distilled from corn in prodigious quantities. During the long nights of winter, spinning flax or wool is the constant occupation of the females, and hence much yarn is produced and sold to other districts.

The trade is chiefly in domestic articles; and these are sent by the rivers or canals in summer, or on sledges in winter, to St Petersburg or Moscow, by merchants residing in the large towns. They are tallow candles, tar, peltry, feathers, isinglass, matts, hogs' bristles, turpentine, potash, and some wooden furniture. There is a transit-trade, by which the productions of Siberia are exchanged with those of Archangel. The number of persons employed in internal navigation is very great; and besides these, others, living on the rivers that are not navigable, are employed in summer in forming rafts of timber, which are floated down by the stream till they reach the barges destined to convey them to the places where the timber is wanted.

The principal rivers are, 1st, The Dwina, which is composed of several rivulets, which, when united, first receives that name within the province. It then receives the waters of the Wytschegda, the Sysola, the Wym, the Keltma, and the Ustjuga. After leaving the province, it is increased by the great stream of the Vaga and its tributary brooks, and runs to the sea at Archangel. 2d, The Petschora, a considerable river rising from the Ural Mountains, and forming a means of intercourse between Tobolsk, Wologda, and Perm. It is navigable during the whole summer, with a depth of from twelve to fourteen feet. There is also a canal, constructed in 1786, which connects the waters of the rivers that run to the Caspian with those that run to the Frozen Ocean. There are many lakes, some of them very extensive. The largest are the Kubenskoe, the Piatisorskoi, the Sandor, and the Rondas. This vast province, which in extent is greater than Britain and Ireland, does not contain more than 940,000 inhabitants. These are divided into nobility, civil officers, clergy, colonists, merchants, citizens and peasants; the last being by far the most numerous. They are in fact slaves, one third of whom belong to the nobility, and two thirds to the crown. The whole of the inhabitants profess the Greek religion, and are under the spiritual government of a bishop, whose see is in the city of Wologda. The capital of the province, and also of a circle, is the city from which it takes its name. It stands on both sides the river Wologda, which divides it into two nearly equal parts, and is without fortifications. It contains fifty-one churches, of which six only are of stone, and the others wooden structures. It has a monastery, a nunnery, an ecclesiastical seminary, some charitable institutions, and public schools for 600 sons of the clergy. The dwellings are 1664, of which all but forty-five are of wood. The inhabitants are 12,100, among whom are many tanners, tallow-chandlers, and some makers of silk, linen, and woollen goods. The commerce chiefly consists of the produce of the soil, or of such manufactured goods as are of the simplest fabrication, which are sent to the seaports in exchange for the few foreign commodities which the condition of society may render desirable. The city is 870 miles from St Petersburg. Long. 40. 6. E. Lat. 59. 13. 30. N.

WOLOKOLAMSK, a circle of the Russian province of Moscow, bounded on the south-west by Smolensko, on the west and north by Twer, and on the other parts by Swenigorod, Rasa, and Moshaik. It extends over 924 square miles, comprehending one city, eighty-one parishes, and 152 hamlets, with 78,600 inhabitants, mostly occupied in agriculture. The soil is moderately fertile. The country is well watered by numerous brooks, and the surface is level and woody. The capital is the city of the same name, on the river Gorodenka, 440 miles from St Petersburg. It is slightly fortified, and has a castle, and contains five wooden and three stone churches, 290 houses, and 3500 inhabitants. It has some trade, from being on a great road. Long. 37. 50. E. Lat. 56. 10. N.

WOLSEY, Thomas, is said to have been the son of a butcher at Ipswich. He studied at Magdalen College, Oxford, where he formed an acquaintance with the learned Erasmus; and in the year 1500 he became rector of Lymington in Somersetshire. He was afterwards made chaplain to King Henry VIII., and obtained several preferments. Having gradually acquired an entire ascendency over the mind of the king, he successively obtained several bishoprics, and at length was made archbishop of York, lord high chancellor of England, and prime minister, and was for several years the arbiter of Europe. Pope Leo X. created him cardinal in 1515, and made him legate *a latere*; and the emperor Charles V. and the French king Francis I. loaded him with favours, in order to gain him over to their interest; but after having first sided with the emperor, he deserted him to espouse the interest of France. As his revenues were immense, his pride and ostentation were carried to the greatest height. He had 500 servants, among whom were nine or ten lords, fifteen knights, and forty esquires. His ambition to be pope, his pride, his exactions, and his political delay of Henry's divorce, occasioned his disgrace. In the earlier part of his life he seems to have been licentious in his manners. It was reported, that soon after his preferment to the living of Lymington in Somersetshire, he was put into the stocks by Sir Amias Paulet, a neighbouring justice of the peace, for getting drunk and making a riot at a fair. This treatment Wolsey did not forget when he arrived at the high station of lord chancellor of England, but summoned his corrector up to London, and, after a severe reprimand, enjoined him six years close confinement in the Temple. Whatever may have been his faults, there can be no doubt of their having been aggravated both by the zealous reformers and by the creatures of Henry VIII., who was himself neither Papist nor Protestant. Wolsey was the patron of learned men, a judge and munificent encourager of the polite arts, and ought to be considered as the founder of Christ Church College, Oxford, where, as well as in other places, many remains of his magnificent ideas in architecture still exist. He died on the 28th of November 1530.

WOLSINGHAM or Walsingham, a market-town of the county of Durham, in the ward of Darlington, 260 miles from London, and fourteen from Durham. It stands on the river Wear, and has a market on Tuesday. The population amounted in 1821 to 2197, and in 1831 to 2239.

WOLTSCHANSK, a circle of the Russian government of Ukraine. It extends in north latitude from 49° 48′ to 50° 32′, and in east longitude from 36° 22′ to 37° 38′. It comprehends one city and 110 towns, besides villages, with 88,400 inhabitants, in a space of 1254 square miles. It has many small rivers, which empty their waters into the Donez. The soil is generally fertile and the climate temperate. The capital is a city of the same name as the circle, and as the river on which it is built. It contains 410 houses, two churches, and 2850 inhabitants. It is 990 miles from St Petersburg. Long. 37. 8. E. Lat. 50. 25. N.

WOLVERHAMPTON, a large town of the county of Stafford, in the hundred of Leisdon, fourteen miles from Birmingham, and 130 from London. It is a place of great antiquity, having in 996 had a school founded by Wulfrina, the sister of King Edgar, and widow of Aldhelm duke of Northampton; previously to which the place was known by the name of Hampton. To honour her memory, her name was prefixed, and it was thus called Wulfrina's Hampton, which, in a series of years, was changed to the name it now bears. During the great civil war, it early declared in favour of the king, and became the head-quarters of the troops commanded by Prince Rupert; but after Charles's final defeat at Naseby, it surrendered to the parliamentary forces.

There are four churches within the town: one of them, dedicated to St Mary and St Peter, was formerly a collegiate institution. It is a spacious cruciform structure, with a handsome tower rising from the centre. The font is of great antiquity, and is most elaborately carved with figures, basses, flowers, and foliage. In the chancel are many curious and ancient monuments. In the church-yard is a column twenty feet high, supposed to be of Danish origin, and exhibiting a profusion of rude sculpture. St John's church is a handsome edifice, in the Grecian style of architecture, with the absurd addition of a tower and a lofty spire. The interior is pleasingly arranged, and is ornamented by a painting of the Descent from the Cross by an artist named Barney, a native of the town. St Paul's church is a perpetual curacy, and was erected at the expense of the present incumbent, who, with another person, is joint patron of the living. St George's is a handsome structure, completed in 1827, under the acts of parliament for building new churches. Besides these, there are places of worship for the several sects of Protestants, a Unitarian chapel, and a chapel for the Roman Catholics. One of the charitable institutions of the town is a free grammar-school, endowed by Sir Steven Jenyns, a native of the place, and lord mayor of London in 1508. It has a liberal endowment of above L.1200 per annum, and has from 150 to 160 boys on its foundation. Among remarkable individuals who received their education in this school, was the late eminent surgeon Mr Abernethy, and Sir William Congreve, the inventor of that most destructive missile which bore his name till it was changed by the artillery into spherical case-shot. There is also another, called the Blue-Coat school, for the inferior classes, in which thirty-six boys and thirty girls are clothed and educated; and most of the churches and chapels have schools attached to them for the gratuitous instruction of children of the labouring classes. There is also a valuable medical dispensary. For amusement and relaxation, a theatre, an assembly-room, a concert-room, and a subscription-library, have been established; and there are annual races on three successive days in the month of August.

The town is favourably situated for the conveyance of the heavy goods fabricated within and around it. It is on the Stafford and Worcester Canal, and on the Essington and Wyrley Canal, upon which there is easy communication with London, Liverpool, and Bristol. The facility of communication has been recently increased by the completion of the Grand Junction Railway, that connects Birmingham with Liverpool and Manchester. The chief trade of the town depends on the mines of iron and of coal which are worked in its vicinity. From them, by mechanical and human labour, are fabricated vast quantities of domestic fire-irons, tinned and japanned iron wares, heavy cast and wrought iron articles, agricultural implements, locks and keys, nails of all sizes, and various other commodities.

The more ancient part of the town is ill built, and has a gloomy appearance; but in the modern part there are some large and handsome dwellings. By the reform bill this place has obtained the right of returning two members to the House of Commons. There are good markets on Wednesdays and Saturdays, and a large fair of three days' duration in the month of May. The boundaries of the parish are very extensive, and comprehend eight other chapelries or townships, in one of which is included the town of Bilston, with, in 1831, 14,492 inhabitants. The population of the town itself amounted in 1821 to 18,380, and in 1831 to 24,732; and that of the parish amounted in 1821 to 36,838, and in 1831 to 48,080.

WOMAT POINT, a rocky projection of Cape Barren island, between Van Diemen's Land and the south-west coast of New Holland.

WOOD, ANTHONY, a well-known literary historian, was the son of Thomas Wood, bachelor of arts and of the civil law, and was born at Oxford on the 17th of December 1632. He studied at Merton College, and in 1655 took the degree of master of arts. He wrote, 1. The History and Antiquities of the University of Oxford; which was afterwards translated into Latin by Mr Wase and Mr Peers, under the title of *Historia et Antiquitates Universitatis Oxoniensis*, 2 vols. folio. 2. *Athenæ Oxonienses;* or an exact Account of all the Writers and Bishops who have had their education in the University of Oxford, from the year 1500 to 1600, 2 fols. folio; which was enlarged in a second edition published in 1721 by Bishop Tanner. This work, which is highly valuable as a collection of materials, has been greatly improved by Dr Bliss. Upon its publication, the author was attacked by the university in defence of Edward earl of Clarendon, lord high chancellor of England, and chancellor of the university, and was likewise animadverted upon by Bishop Burnet; upon which he published a Vindication of the Historiographer of the University of Oxford. He died at Oxford on the 29th of November 1695.

WOOD, a substance of which the trunks and branches of trees consist. See PLANTING, TIMBER, and VEGETABLE PHYSIOLOGY.

WOOD, *Fossil.* Fossil wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth, and sometimes in small pieces loose among the gravel. These, according to the time they have lain in the earth, or the matter they have lain among, are found differently altered from their original state; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone, or lumps of the common matter of the pyrites, &c. of the dimensions, and more or less of the internal figure, of the vegetable bodies into the pores of which they have made their way. See GEOLOGY.

WOOD-ENGRAVING is the art of representing objects on wood, by lines and points, in order to their being impressed on paper. This art is of very ancient date, having been practised by the Egyptians. Some bricks found on the site of ancient Babylon are preserved in the British Museum, with characters upon them which have plainly been indented from engraved blocks of wood. It appears also, from specimens that are extant, that the Greeks and Romans were acquainted with methods of wood-cutting for impressing letters and characters on various substances. The probability of the art being known to the Chinese, or actually having been carried to the extent of delineating figures, in the thirteenth century, has been successfully disproved by Mr Jackson, in his able and learned Treatise on Wood-Engraving. The art was however used in the thirteenth and fourteenth centuries for attesting documents, and about the commencement of the fifteenth century, by the Germans, for marking figures on playing-cards.

The most ancient wood-cut of which there is any authentic account, is that of *St Christopher* carrying an infant Christ through the water, now in the possession of Earl Spencer. It is eleven and a quarter inches high, and eight and one eighth inches wide. The impression is dated in 1423; and the figures of the saint and the youthful Saviour are executed with very considerable spirit and feeling. Wood-cuts of the *Annunciation* and of *St Bridget of Sweden* appear to belong to this period, when the art began to be much encouraged by the church. Heineken, in allusion to this, tells us, that "having visited in my last tour a great many convents in Franconia, Suabia, Bavaria, and in the Austrian states, I everywhere discovered in their libraries many of those kinds of figures, engraved on wood, and pasted either at the beginning or the end of old volumes of the fifteenth century. I have indeed obtained several of them. These facts, taken altogether, have confirmed me in my opinion, that the next step of the engraver in wood after playing-cards, was to engrave figures of saints, which, being distributed and lost among the laity, were in part preserved by the monks, who pasted them in the earliest printed books with which they furnished their libraries."

Between 1430 and 1450, several works technically called block-books, chiefly illustrative of the Scriptures, appeared. The most remarkable among these is the *Apocalypse, or History of St John*, which was probably engraved in 1434, and is reputed to have been the production of Laurence Coster, a Dutchman. According to Heineken, there have been six editions of this book. "Though some of the designs," Jackson observes, "are very indifferent, yet there are others which display considerable ability, and several of the single figures are decidedly superior to any that are contained in the other block-books. They are drawn with greater vigour and feeling." The figures in another of these block-books, called the *History of the Virgin*, are also very gracefully delineated, and the style in which the cuts are engraved exhibits a more advanced stage of the art than we find in the *Apocalypse.* Another specimen of block-books is called the *Biblia Pauperum* (see Plate CCCCXIII. art. PRINTING), the figures it contains having, it is conjectured, been executed for the purpose of imparting a knowledge of sacred history to those who could not afford to purchase a manuscript copy of the Scriptures. Several of the cuts in this work, though rude, are not inexpressive of the scenes which they represent. The *Alpha-*

Wood-Engraving.

bet, composed of grotesque figures from wood engravings, was probably executed about the middle of the fifteenth century; and Jackson, judging from their style, thinks that they are the work of a native of France.

Wood-engraving began to be combined with printing after the invention of the latter art, in the fifteenth century. In the *Psalter*, printed by Faust and Schœffer at Mentz in 1457, the large initial letters engraved in wood are so beautiful that they have never been excelled. From the perfection which these letters exhibit, it is evident that the workmen were trained to the art. The practice of introducing wood-cuts became general in Germany, and was known in Italy, towards the end of the fifteenth century. The first books in the English language containing wood-engravings were those printed by Caxton about 147 The use of cross hatchings (which are black lines crossing each other generally diagonally) produced a great change in the art, giving colour and shadow to the subject.

The next attempt at improvement in this art was by Hugo da Carpi, to whom is attributed the invention of *chiaroscuro*. Carpi was an Italian; but the Germans also claim the invention, and produce in evidence several engravings by Mair, a disciple of Martin Schoen. His mode of performing this was very simple. He first engraved the subject upon copper, and finished it as much as the artists of his time usually did. He next prepared a block of wood, upon which he cut out the extreme lights, and then impressed it upon the print; by which means a faint tint was added to all the rest of the piece, excepting only in those parts where the lights were meant to predominate, which appear on the specimens extant to be coloured with white paint. The drawings for this species of engraving were made with a pen on tinted paper, and the lights were drawn upon the paper with white paint.

But there is a material difference between the chiaroscuro of the old German masters and that of the Italians. Mair and Cranach engraved the outlines and deep shadows upon copper. The impression taken in this state was tinted over by means of a single block of wood, with those parts hollowed out which were designed to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, to cut the outline on one block of wood, the dark shadows upon a second, and the light shadow, or half-tint, upon a third. The first being impressed upon the paper, the outlines only appeared. This block being taken away, the second was put in its place, and being also impressed on the paper, the dark shadows were added to the outlines; and the third block being put in the same place upon the removal of the second, and also impressed upon the paper, made the dim tints, when the print was completed. In some instances the number of blocks was increased, but the operation was still the same, the print receiving an impression from every block.

Albert Durer, towards the end of the fifteenth and commencement of the sixteenth century, was the great promoter of wood-engraving. It is supposed that many of the wood-cuts, though bearing his name, were only engraved from drawings made on the block by him. "One of the peculiar advantages of wood-engraving," Mr Jackson observes, "is the effect with which strong shades can be represented; and of this Durer has generally availed himself with the greatest skill. On comparing his works engraved on wood with all those previously executed in the same manner, we shall find that his figures are not only much better drawn and more skilfully grouped, but that, instead of sticking, in hard outline, against the back-ground, they stand out with the natural appearance of rotundity. The rules of perspective are more attentively observed, the back-grounds better filled, and a number of subordinate objects introduced, such as trees, herbage, flowers, animals, and children, which at once give a pleasing variety to the subject, and impart to it the stamp of truth. Though the figures in many of his designs may not indeed be correct in point of costume,—for though he diligently studied nature, it was only in her German dress,—yet their character and expression are generally appropriate and natural. Though incapable of imparting to sacred subjects the elevated character which is given to them by Raffaele, his representations are perhaps no less like the originals than those of the great Italian master."

Besides Durer, there were Burgmair, Cranach, Schaufflein, and other German artists of celebrity, who engraved on wood. At this period the best wood-engravings were of considerable size, and designed in a bold and free manner; and at no time was the art more encouraged and esteemed. Hans Holbein, in 1538, produced the *Dance of Death*, in a series of wood-cuts, which for truth and freedom of execution has never been surpassed. "The manner," Mr Jackson remarks, "in which they are engraved is comparatively simple; there is no laboured and unnecessary cross-hatching where the same effect might be obtained by simpler means; no display of fine work merely to show the artist's talent in cutting delicate lines. Every line is expressive, and the end is always obtained by the simplest means. In this the talent and feeling of the engraver are chiefly displayed. He wastes not his time in mere mechanical execution, which in the present day is often mistaken for excellence; he endeavours to give to each character its appropriate expression; and in this he appears to have succeeded better, considering the small size of the cuts, than any other wood-engraver, either of times past or present."

Wood-engraving now made considerable progress in Italy, particularly in Venice; and the engravings of this period in that country were little inferior to the German works. The art rather declined on the eontinent about the end of the sixteenth century, when copperplate engraving came into use. In England, it continued to flourish, as several works of the time show. Jegher of Antwerp, who was born in 1578, was so eminent in the art, that he was employed by Rubens to work under his inspection; and he executed several pieces which are held in much estimation. They are particularly distinguished for boldness and spirit. Towards the end of the seventeenth century, wood-engraving was greatly neglected, and was employed only for common decorations, and never almost to delineate any subject of interest.

About the year 1723, John Michael Papillon produced many successful works in wood-engraving, particularly ornamental foliage, flowers, and shells. In 1766, he published his History of Wood-Engraving, the cuts in which are his own workmanship. The book, although deficient in many respects, evinces a laudable diligence in bringing the art into more extended employment.

Wood-engraving was for many years in a very degenerate state, and almost wholly lost, till it was revived in England by the celebrated Thomas Bewick. This artist was born in the parish of Ovingham, in Northumberland, in 1753. Having shown a taste for drawing, he was entered apprentice with Mr Ralph Beilby, engraver, at Newcastle-upon-Tyne; and in 1775 he had made such progress as to obtain a premium from the Society of Arts for his wood-engraving of the "old hound." He afterwards produced his well-known History of Quadrupeds, which was succeeded by his History of British Birds and other standard works, which brought him so much celebrity, that he was universally hailed as the reviver as well as improver of the art. His great excellence was the singular fidelity of his designs. "It needs only to glance at the works of Bewick," observes an anonymous writer, "to convince ourselves with what wonderful facility the very countenance

Wood-Engraving.

and air of his animals are marked and distinguished. There is the grave owl; the silly, wavering lapwing; the pert jay; the impudent, overfed sparrow; the airy lark; the sleepy-headed gourmand duck; the restless titmouse; the insignificant wren; the clean, harmless gull; the keen, rapacious kite; every one has character. There are no 'muffin faces.' This is far beyond the mere pencilling of fur or feathers; it is the seizure and transfusion of countenance. In this Bewick's skill seems unapproached, and unapproachable, by any other artist who has ever attempted this line." This was written in 1825, during the lifetime of Bewick; and since that time, although he has perhaps been surpassed by some of his pupils in mechanical skill, none has equalled him in his truthful conception and delineation of nature.

John Bewick, brother to Thomas, acquired the art from him, and practised it in London for several years. His abilities, though respectable, were not so brilliant as those of his brother. His cuts have not the same interest, and his style of engraving is not considered very good. He died in 1795, aged thirty-five. His more illustrious brother Thomas lived till 1828, and continued to ply his art till within a short time of his death. Wood-engraving is much indebted to this famous artist, not only for the excellence to which he brought it, but for the taste he created for such productions; a taste which has been maintained by the many admirable works of his pupils, and other artists of the present day. Of late, wood-engraving has made considerable progress in Germany and France.

The wood generally used by wood-engravers is box, which, from its hardness and toughness, bears the action of the press better than any other; and the smallest kinds, being the most compact, are preferred. The blocks are cut directly across the grain. Before the drawing is made, the block is rubbed over with Bath-brick and a little water. If the drawing is a delicate one, the block, except the place where the artist commences, is covered with paper. The habit of using magnifying glasses is not recommended to beginners.

There are four kinds of cutting tools used in wood-engraving, *gravers*, *tint-tools*, *gouges* or *scoopers*, and *flat tools* or *chisels*. The *gravers* are of various sizes, and are employed for the principal part of the work. What are called *tint-tools* are chiefly for cutting parallel lines. *Gouges* are for scooping out the wood towards the centre of the block, and *chisels* for cutting away the wood towards the edges. The printing press is employed in taking impressions from an engraved block of wood. "The block," according to Mr Jackson, "is inked by being beat with the pressman's balls or roller, in the same manner as type; and the paper being turned over upon it from the *tympan*, it is then run in under the *platten*, which being acted on by the lever, presses the paper *on to* the raised lines of the block, and thus produces the impression. Impressions from wood are thus obtained by the *on-pression* of the paper against the raised or prominent lines."

Wood-engraving is now generally used in illustrating publications of all kinds. "In the child's first book," Mr Jackson observes, "wood-cuts are introduced, to enable the infant mind to connect words with things. The youth gains his knowledge of the forms of foreign animals from wood-cuts; and the mathematician avails himself of wood-engraving to execute his diagrams. It has been employed, in the representation of religious subjects, as an aid to devotion; to celebrate the triumphs of kings and warriors; to illustrate the pages of the historian, the traveller, and the poet; and, by its means, copies of the works of the greatest artists of former times have been afforded, at a price which enabled the very poorest classes to become purchasers. As at least one hundred thousand good impressions can be obtained from a wood-cut, if properly engraved and carefully printed, and as the additional cost of printing wood-cuts with letter-press is inconsiderable when compared with the cost of printing steel or copper plates separately, the art will never want encouragement, nor again sink into neglect, so long as there are artists of talent to furnish designs, and good engravers to execute them." The great utility of wood-engraving will indeed, in all probability, prevent the art from ever again declining. Within these few years it has attained a very high degree of perfection; and every day, works are issuing from the press, adorned with the most varied specimens of this valuable art. (Z. Z.)

Woodah | Woody Island.

WOODAH, a long curved island in the Gulf of Carpentaria, on the west coast, extending about thirteen miles in length. Lat. of its northern point, 13. 22. S.

WOODBRIDGE, a market-town of the county of Suffolk, in the hundred of Loes, eight miles from Ipswich and seventy-eight from London. It is situated on the navigable river Deben, and has some ship-building, and some trade by sea with London, Newcastle, and Hull. The principal streets are well built and well paved. The parish church is a fine structure, built of black flints, and has a tower 180 feet in height, which serves as a sea-mark. There is a large market on Wednesday, chiefly for corn. The population amounted in 1821 to 4060, and in 1831 to 4769.

WOODCHESTER, a town of the county of Gloucester, in the hundred of Longtrees, 104 miles from London. It is a manufacturing place for broad cloths, but the trade is on the decline. There is an endowed grammar school; and near to it is the magnificent seat of Lord Ducie. The population amounted in 1821 to 929, and in 1831 to 885.

WOODWARD, John, was born in Derbyshire, on the 1st of May 1665. He was educated at a country school, where he learned the Latin and Greek languages, and was afterwards sent to London, where he is said to have been put apprentice to a linen-draper. He was not long in that station till he became acquainted with Dr Barwick, an eminent physician, who took him under his tuition and into his family. Here he prosecuted with great vigour and success the study of philosophy, anatomy, and physic. In 1692, Dr Stillingfleet quitting the place of professor of physic in Gresham College, Woodward was chosen to succeed him, and the year following was elected F.R.S. In 1695 he was created M.D. by Archbishop Tenison, and in the following year he was admitted to the same degree at Cambridge. His principal work is entitled "An Essay towards a Natural History of the Earth and Terrestrial Bodies, especially Minerals." Lond. 1695, 8vo. A Latin translation of it appeared at Zürich in 1704; and in 1714 he published "Naturalis Historia Telluris illustrata et aucta." He wrote many other pieces, which were well received by the learned world. He founded and endowed a professorship of natural history in the university of Cambridge; and this chair was first occupied by the celebrated Dr Middleton. Dr Woodward died in Gresham College, on the 25th of April 1728.

WOODY Head, a high cape on the coast of New Zealand, in the South Pacific Ocean. Lat. 37. 42. S.

Woody *Island*, an island in the Eastern Seas. Long. 106. 5. E. Lat. 1. 46. N.

WOOL, AND ITS MANUFACTURES.

The word wool is usually employed to designate the *pile* of the sheep and of some other animals. It may be defined a species of hair, but it is distinguishable from ordinary hair properly so called, by being much more soft and flexible, and by possessing in a superior degree the property of felting, which we shall hereafter have occasion to describe. It is sometimes difficult to exprcss that with which most people are familiar; and yet, as popular conception is often inadequate and incomplete, further description becomes necessary. This is especially the case with regard to wool. We all seem at first sight to perceivc the distinction between wool and hair. In ordinary cases, like light and darkness, they are sufficiently distinguishable. The bristles of the hog stand at a wide distance from the soft pile of the Saxon lamb. Yet, in many intermediate cases, it would be hard to say what is the one and not the other. There are some animal coverings which seem to stand between the two extremes; the hair of some goats and the wool of some sheep seeming entirely to change characters.

Most of the furred animals have, in a state of nature, both hair and wool; the hair long and conspicuous, forming the outer coating of the animal; and the wool short, soft, and down-like, and lying hidden bencath the coarser hair. In the beaver this is very conspicuous. To all outward appearance it is a coarse-haired animal; and it is not until the long hair is plucked that the soft wool used in the manufacture of hats becomes visible. The skin of the racoon, of the wild cat, and even of the otter, coarse as its outer hair appears, produces wool; and the finer fleece of the rabbit, called *coney's* wool, is well known in commerce.

We also apply the term wool to the fibre of the cotton plant (see COTTON MANUFACTURES), an application which was not unknown to the Mantuan bard:

> —— nemora Æthiopum molli canentia *lanâ*.

In the present article we shall confinc ourselves to a description of the wool of the sheep, and its properties; and especially to its manufacture into woollen cloths and worsted stuffs.

The original stock of the several varieties of sheep is said to be the Argali (*Ovis ammon*), which is still found wild on the mountains of Siberia and Kamtschatka. This seems to be scarcely distinguishable from the Moufflon (*Ovis aries*), or wild sheep of the mountain districts of Sardinia, Corsica, and Asia Minor. But its fleece, which is coarse as well as short, resembles hair rather than wool; and it is not until improved by culture that its covering assumes the woolly character.

The effects of a more temperate climate, of more regular and better pasture, and especially of careful shelter from the inclemencies of thc weather, are indeed very remarkable. The coarser hair gradually disappears, and the shorter and finer wool which we have described as investing the skin of various animals, becomes more abundantly developed.

In modifying the physical character of animals by breeding, it is well known that the dam has more influence over the form and other peculiarities of the progeny than the sire; yet, as regards the quality of the wool, the order is reversed, and the sire has been ascertained to act the more conspicuous part. In the first place, the ram more rapidly undergoes the change above mentioned when subjectcd to man's care; and in the second, he imparts to the wool of the progeny a greater share of fineness than an improved ewe would do. Thus it has been laid down by those who have had great experience in the breeding and crossing of sheep, that a fine-woolled ram and a coarse-woolled ewe will produce lambs with wool three fourths instead of half as fine as the wool of the sirc; whilst a coarse-woolled ram and a fine-woolled ewe will produce lambs with wool only one quarter as fine as that of the sire. To keep up the quality of wool, therefore, the finest-woolled rams must be continually introduced, otherwise deterioration cannot be avoided. This is well understood in all the wool-growing countries. In Germany very high prices are given for fine-woolled rams; and in Australia, the newest field for wool-growing, the attention of flock-masters is fully alive to the same fact.

The removal of the coarse woolled is an object of equal importance. Even among the best flocks coarse-haired varieties will spring up from mere peculiarities of constitution. This is especially the case in our changeable climate, where the sheep are liable to be affected by sudden changes of temperature. If the removal of such sheep is not at once attended to, the flock will materially deteriorate in a very few generations.

But although deterioration soon becomes obvious, the superior character of a particular breed of sheep will be perceptible in particular localities, even after the lapse of ages; and it is not a little remarkable, that the vestiges of the finer-woolled animals is still to be traced in localities which were formerly the seats of manufacture. Angora, for instance, the ancient *Ancyra*, still retains the fine-fleeced goat; and the cat and the rabbit of that district still produce a wool remarkable for its fineness, its softness, and its length. The fine-woolled sheep of Tarentum, so much valued by the Greeks and Romans, originally came from Asia Minor, where the traces of similar animals are still to be met with; and the descendants of the same breed, conspicuous even in their degeneracy, form the common stock of Sicily and the southern parts of Italy.

This permanency in the character of the breeds of sheep is doubtless partly owing to food and climate. The effect of pasturage on the fleece is well known. The experiments that have been made in this country have placed it beyond a doubt. The wool of sheep fed in chalky districts will be greatly inferior to that of sheep of similar character pastured on land more congenial to the growth of soft wool; and it is even said, that where flocks have been fed on bad herbage, and their fleeces are harsh, considerable improvement will take place by removing them to better pasture, if it be only for a single month previously to shearing. In that case "the bad effects of any late herbage will be counteracted, and the fleeces of their flocks will handle soft, and increase in weight, and consequently in value."[1]

"By way of example," says the author we have just quoted, "we will suppose half a flock of South-Down sheep, reared in the centre of the South Downs (known to be calcareous and chalky land), and the other moiety transferred to some of the rich land found in the neighbourhood of Pevensey Level, near Lewes. The contrast that would be perceptible in the fleeces of these two portions of the same flock when shorn, is inconceivable to those who have not had an opportunity of witnessing the powerful influence of a change in pasture on the wool of sheep.

"Both the temperature of climate, and herbage, have an evident effect on wool, as may be seen in England on that of those flocks pastured within a few miles of the sea-coast, beginning with the Isle of Sheppey, round the coast of Kent, Sussex, and Hampshire. The wool of flocks which are fed within ten miles of the sea-coast generally possesses a longer staple, and more pliancy of texture, and consequently it is better adapted to the use of the spinner, than the produce of the same flock pastured farther in the interior on similar soil. This difference I am disposed to impute to the exhalations arising from the sea, which, like the smoke of London, extend inland at least ten miles, thus operating on the herbage as well as on wool."[1]

---

[1] Southey's Treatise on Sheep, 1840, p. 14.

Of all the varieties of which wool is susceptible, the length of the staple is the most important in its results. Wool is accordingly divided into two classes, short or clothing wool, and long or combing wool, each class being subdivided into a variety of sorts, according to their fineness, and the length and soundness of the staple.

The finest wools are of short staple, so that the worsted spinner has sometimes difficulty in obtaining wools fine enough for the more delicate fabrics; but man's ingenuity has found a remedy for this, by combing wools of much shorter staple than was formerly deemed possible. In the case of the coarser wools there is no such difficulty, as they are usually of long staple. Wools which unite a high degree of fineness and softness with considerable length of staple, bear a high price.

The sorting of wool is the business of the wool-sorter, a trade which requires the nicest discrimination. Such is the tact which habit gives, that the most skilful sorter can appreciate differences which even the microscope can scarcely detect; and in appreciating the other qualities of the fleece, and weighing and balancing one against the other, a degree of accuracy is attained of which no instrument is capable. Of minute differences of quality, and of the result or balance of all the qualities taken together, the price of wool is perhaps the best measure, and we shall therefore presently advert to it more fully.

The principal qualities which the sorter regards in short or clothing wools may be stated as follows:

1. The fineness of the fibre.
2. Its softness.
3. Soundness of the staple.
4. Colour.
5. Clean state of the fleece.
6. Weight.

1. The fineness of the fibre is of very great importance. Modern machinery is capable of producing a finer thread from coarser wools than formerly, and the thinner and lighter fabrics can be made from it; but unless the wool be also fine, no art can make a fine, compact, and even cloth. This will be readily understood when we come to describe the process by which a surface is produced; a surface which consists wholly of the ultimate fibres of the wool.

Besides the fineness of the fibre, its regularity is of great importance. There are some kinds of wool which are only fine at the lower end near the back of the animal, while the extremity of the wool is coarse and hairy. There is perhaps no wool in which some irregularity is not perceptible, though it is much more conspicuous in some samples than in others. *Cæteris paribus*, the value of two samples will depend on evenness or regularity, and it is for this quality that the wool of the Merino sheep is so remarkable.

In some fleeces of the finer sorts, an admixture of coarse hairs will often be visible; in some cases, long and silvery; in others, short and rigid: these latter are technically called *kemps*. We do not remember to have seen the cause suggested, but we apprehend that this may merely be a mark of age. In the human eyebrow, for instance, it is well-known that long coarse hairs make their appearance even before the meridian of life; and it is by no means improbable that age may have some connexion with a similar phenomenon in the wool of sheep. When the wool is uniform, it is said to be *true grown*.

The finest Merino fleeces are usually divided into four sorts; the first three being called by the Spaniards *refina*, *fina*, and *tercera*; the fourth or coarse part, from the head and shanks, not being sent to market. The distinctions of quality in German and other wools will afterwards be specified.

In English fleeces, however, the proportions are different, the finest portion seldom exceeding one third; but our English sorters discriminate qualities much more nicely, making of the whole fleece no less than eight or ten sorts, varying perceptibly from each other in fineness, and known by the following names:

Prime.
Choice.
Super.
Head.
Downrights.
Seconds.
Fine Abb.
Coarse Abb.
Livery.
Short coarse or breech wool.

Some sorters will even select from the prime sort the few remarkably fine locks which they may find, and so make a very superior sort, which they call *pick-lock*.

It is said that the very nice discrimination which the wool-sorter attains by constant practice is considerably impaired if the practice be discontinued for a short period. It follows that both the buyer and the seller, the manufacturer and the grower, must frequently err in their judgment respecting the comparative qualities of particular samples. Various attempts have accordingly been made to determine the fineness of the fibre by means of instruments; but, admitting that accuracy is attainable by their means—a very doubtful point—their use can never become general, as the art of using instruments would probably be more difficult of attainment by the Leicestershire wool-grower or the Yorkshire manufacturer than the art of sorting wool.

The individuals who have taken the most trouble to ascertain the fineness of wool by means of instruments are Dr Parry, Mr Luccock, and Dr Ure. These instruments consist of a micrometer and a lens; and they differ from each other only in the mode of application and adjustment. The result of these experiments seems to be, that the finest wools are about $\frac{1}{1300}$ of an inch in diameter, while the coarsest of the combing wools are about $\frac{1}{450}$ of an inch. Dr Parry's table of the diameters of clothing wools, which has often been printed, is as follows.

Table of comparative Diameters of various Clothing Wools.

	Outward End.	Middle.	Inner End.	Mean.
Spanish ewe	$\frac{1}{1232}$	$\frac{1}{1433}$	$\frac{1}{1468}$	$\frac{1}{1370}$
Lasteria pile	$\frac{1}{1146}$	$\frac{1}{1216}$	$\frac{1}{1472}$	$\frac{1}{1264}$

---

[1] Southey's Treatise on Sheep, p. 14.

Dr Ure in 1837 made a series of experiments on different wools, and published the results. He found that the filaments of the finer qualities varied in diameter from $\frac{1}{100}$ to $\frac{1}{1500}$ of an inch, which agrees pretty nearly with Dr Parry's table.

2. The softness of the wool is a quality of not less importance than its fineness, the more especially as the perfection of the felting property mainly depends upon it. This quality is easily distinguishable by the touch, both in the raw wool and in the finished cloth, which, when made from soft wool, is itself extremely soft. Such cloth bears a much higher price than cloth equal in other respects, but made from harsher wool.

Of all the European wools, that of Saxony seems to be pre-eminent in point of softness. When England only imported about 2,500,000 lbs. of wool from Germany, "Saxony cloth bore a very high price in proportion to cloth from all other kinds of wool; but now that Germany affords us nearly 30,000,000 lbs., the supply reaches the demand, and the price is not excessive.

All the European wools yield to that of India in respect of softness. It is grown on sheep of small size, the wool of which is short and soft near the skin, with long coarse wool or hair growing through it, similar to what we have described in the case of the beaver and other furred animals. It should be observed, that it is chiefly upon the softness of the wool that the *felting* property depends; but as we shall hereafter have occasion to speak more fully of that property, we now proceed to the quality next in order.

3. What is called the *soundness*, which is only another name for the strength of the staple, is obviously of less importance in clothing wool than in combing wool. Still it is not wholly disregarded in the former, as the durability of the surface of the cloth will mainly depend upon it.

4. The colour of the fleece, that is, its whiteness, is obviously an essential quality, whether for white cloth or for light and bright colours. Indeed even the darkest colours are probably richer, and possess more lustre on a clear white ground, than when the wool is dark or mixed. Black and brown woolled sheep are not uncommon in most of the countries of Europe; but their wool is of less value, and there can be no object in encouraging the breed. The black-faced sheep of Norfolk, which is also to be met with in other English counties and in Scotland, and which produces fine wool, has this defect, that dark fibres are frequently to be met with. In Canada, the whole of the peasantry is clothed in a domestic cloth, called by the inhabitants *étoffe du pays*, which is made of a mixture of black and white wool.

The Romans were particularly careful in expelling the dark-woolled sheep from their flocks; and we are told by Virgil, that they even examined the tongue and palate of the rams, and if they exhibited any blackness, such sheep were rejected. It is said that a dark soil imparts a tint to wool which renders it wholly unfit for white or any bright cloth.

5. The cleanness of the wool is another quality which the purchasers cannot disregard, as its influence on weight is so conspicuous. Here however there is a difficulty, which requires a very nice balancing of opposite and conflicting qualities, and which demands explanation. All wools, as they come from the sheep's back, are more or less greasy to the touch. The cause of this greasiness is the presence of a peculiar kind of potass soap, secreted by the animal, and called by the farmers the *yolk*. The softness and flexibility of the wool depends almost wholly on the abundance of the yolk; yet as it readily forms a lather with water, and does not add to the value, but only increases the weight of the fleece when shorn, it should be washed out. In Britain this is done before shearing; but this is not sufficient to get rid of the yolk in any sheep, and especially in Merinos.

The grease, although so necessary to the softness of the living fleece, has been found to be injurious to the wool when shorn; as a sort of fermentation takes place, and the fleece is rendered hard and harsh by the very substance which softens it while living.

After this explanation, the reader will perceive that, as far as mere weight is concerned, the grower is interested in washing out as small a quantity of the yolk as possible, while the buyer is interested in having the wool as well washed as possible. Both are interested in the presence of a good yolk originally, as the quality of the wool is thereby improved. Fermentation from imperfect washing is not uncommon. If this proceed to a great extent, the wool is injured; but a moderate degree of fermentation is said to render the wool better suited to manufacture.

6. The weight of the fleece is a quality of the utmost importance to the grower; but it must not be obtained by the sacrifice of fineness or of cleanness. Weight, as we have seen, may arise from the presence of yolk. It may also arise from coarseness; and even where it arises from length of fibre, that is a quality which generally supposes a certain degree of coarseness. An abundant supply of food will sometimes increase the length of the staple; but if this be accompanied by increased coarseness, as it generally is, it is not to be desired. What the grower wants, and what the buyer cannot object to, is that weight of fleece which arises from the closeness of the pile on the back of the animal; a quality which supposes greater fineness, and generally greater softness, though usually accompanied by extreme shortness of staple.

With regard to long wool, or combing wool, as it is indifferently called, the desirable qualities are the same, with the addition of *length of staple*, which stands at the head of all. Very great length of staple was formerly of more importance than it has been of late, because the mode of combing wools of moderate length was not known. We have seen accounts in old annual registers and magazines, of wool of twelve, sixteen, and even twenty inches staple; but that could only be produced by leaving the sheep two years unshorn. We have however now lying before us wool of eleven inches staple, but it is extremely harsh and coarse. The usual length of combing wool is from three to eight inches; but wool of two inches can now be combed, which admits of the use of very *fine* and *soft* wools, provided they be of *sound staple*, for the production of the finer Merinos, mousselines de laine, and the better sorts of hosiery.

As the comber dispenses with length, soundness of staple becomes extremely important. Without soundness, the short and fine wools would not bear the operation of the comb; with it the skilful comber will now venture upon wools, to comb which would a few years since have been deemed an impossibility.

The other qualities of wool,—colour, *i. e.* whiteness, cleanness, *i. e.* freedom from yolk, and weight,—are of as much importance in combing as in clothing wools, subject, of course, to the pre-eminence of the other qualities which we have enumerated.

We now come to consider the *sources of supply*, that is, the various wool-growing countries whence the large demand of Great Britain has been and is satisfied.

Various estimates have been made of the number of sheep in Great Britain, and of the quantity of wool produced; but the earliest which enjoys any reputation for accuracy is that of Mr Luccock, in his Treatise on English Wool, in 1800. According to his very minute calculation, the quantity of wool produced in England alone in 1800 was 384,000 packs, of 240 lbs. each, or 92,160,000 lbs. It is thought that the number of sheep has not greatly increased since; but Mr Hubbard, who in 1828 submitted to the Lords'

Committee some tables on the plan of Mr Luccock's, arrived at the conclusion that, owing to the increased weight of the fleeces, the quantity of wool produced had at that time increased to 463,169 packs. Taking Scotland and Ireland into account, the total quantity of wool is estimated by Mr M'Culloch at 520,000 packs, or 124,800,000 lbs. The sheep in Great Britain and Ireland are estimated at 32,000,000.

The following table exhibits the quantity of long and short wool produced in each county of England in 1800 and 1828, according to Luccock and Hubbard.

Number of Sheep and Quantity of Sheep's Wool produced in England, according to Mr Luccock's Tables, revised by Mr Hubbard, and made applicable to 1828.

County.	1800.					1828.

From the reign of Charles II. until the year 1825, the exportation of British wool was prohibited, under an impression that our wool was superior to all others, and that if we kept it in the country, foreigners would be compelled to come to us for manufactured woollens. During the early part of the last century, numerous pamphlets issued from the press for and against that mischievous policy; and the offence of *running wool* prevailed to a great extent. These pamphlets are noticed in Smith's Memoirs of Wool, and the absurdity of the prohibition is exposed in a manner which certainly anticipated the general current of the political and economical knowledge of that age.

The prevalence of this disposition to export wool in spite of severe laws, affords a proof that our production of wool was in advance of our means of working it up. We were in fact an agricultural nation, and it was not until our spinning machinery was improved, and our skill became rapidly developed, that the tide may be said to have turned.

Towards the end of the last century, as will be seen by the table we shall presently exhibit, England began to be an importer of wool. Laws prohibiting the "running of wool" then became a dead letter; and before 1800, we were annual importers to the extent of 4,000,000 lbs., our whole demand being about 100,000,000 lbs. At this period, however, the landowners began to take the alarm, and a duty, a mischievous duty, of 5s. 3d. per cwt. was imposed on all foreign wool imported into Great Britain. In 1813 the duty was raised to 6s. 8d. per cwt.; and in 1819 Mr Vansittart (Lord Bexley), perhaps the most ignorant and vulgar-minded minister that ever managed, or rather mismanaged, the financial affairs of this realm, raised the duty to 56s. per cwt., or 6d. per lb. The effect of this was simply to deteriorate the quality of British manufacture. To produce the finer cloths, foreign wools were absolutely necessary. When Mr Vansittart imposed this duty, the soft Spanish wools were much used in the clothing districts and the Saxony wools were coming into use. (See the next table.) The English wools were utterly unfit for the production of our finest cloths; and our exports, in consequence of the virtual prohibition of foreign wools, showed symptoms of decline. In 1824 the duty was reduced to 3d., and at the end of the same year to 1d. In July 1825 the duty was further reduced to ½d. on wools under 1s. in price, being continued at 1d. on wools at and over 1s., at which rates the duties have since remained. This reduction has produced the most beneficial effects, not merely on manufactures, but also on the steady price of English wools, which have been much higher on the average since the reduction than they were before, although we have become importers to the extent of half the whole quantity we consumed when Mr Vansittart's tax was imposed. The reduction of this impolitic duty has in fact been one of the causes by which our manufactures have so rapidly increased since 1826.

Having said thus much of the quantity of English wool consumed in the manufactures, we now come to the history of our foreign importations.

We have already stated, that before the end of the last century, our production, in point of quantity, was greater than the amount of our wants. Importation up to 1803 having been free, some small quantity of foreign wool found its way into this country; but it was only an exchange of one quality for another, and our real demand previous to 1800 was exceedingly small. Our whole importation, in fact, only averaged 4,000,000 lbs., the greater part of which consisted of the fine soft clothing wool of Spain.

The year 1800 exhibited an increase to nearly 9,000,000 lbs., of which 6,000,000 was still received from Spain, and nearly 1,500,000 from Portugal. This went on until the peace, when an increased quantity of Saxon wool came into the English markets. The Merino breed of sheep had been introduced into Saxony by the elector, afterwards king of that state, and with most signal success. During the war, our imports from Germany had never reached 1,000,000; in 1815 they exceeded 3,000,000, and the quantity has since increased, so as to exceed 25,000,000 lbs. in the average of years, while the quantity of Spanish wool has progressively declined. These changes, and the general progress of our importations of foreign wool, will be best exhibited by the following table, giving the importations in periods of five years from 1796 to 1835.

Table showing the principal Sources of Supply of Foreign Wool from 1796 *to* 1835.

Year.	Spain.	Germany.	New South Wales.	Other Countries.	Total.
1796 1799	3,300,000	300,000	...	400,000	4,000,000
1800	6,062,824	412,394	...	2,140,066	8,615,284
1805	6,858,738	36,787	...	1,645,751	8,541,276
1810	5,952,407	778,835	167	4,264,315	10,936,224
1815	6,927,579	3,137,438	...	4,926,696	14,991,713
1820	3,536,227	5,113,242	99,415	1,324,860	10,073,746
1825	8,206,472	28,799,660	323,995	5,507,734	42,837,861
1830	1,643,513	26,073,882	1,967,309	2,628,355	32,313,059
1835	1,602,752	23,798,186	4,210,310	12,563,276	42,174,523

The great change that is now going on, however, consists in the rapid increase in the supply of wool from Australia; a change which the above table exhibits to a certain extent, but which the more detailed comparison we are about to offer will place in a more conspicuous light.

The first person who became impressed with the peculiar fitness of New South Wales for the growth of wool was Captain John Macarthur, one of the most intelligent and energetic of the early settlers in that colony. He there commenced farming operations in 1793, but his only sheep at that time were Bengal ewes, whose wool is extremely coarse. About two years after, he procured a Merino ram from the Cape, with two ewes of the same breed, and with these he began crossing, and selecting the finest-woolled rams to breed with, so as continually to improve the wool on the principle pointed out in the early part of this article.

In 1802, he brought specimens of his wool to England, which being approved by some experienced cloth manufacturers, he obtained a hearing before the privy council. He obtained an additional grant of land in a very fertile part of the colony, and with three fine-woolled Merino rams and two ewes he returned to the colony to prosecute his favourite plan. It is scarcely necessary to state, that the most extraordinary success has attended the breeding of sheep; and the wool is said to be equal, when perfectly clean, to the Merino wools of Saxony, and would sell for as high a price, but for the little care taken in washing previously to shearing. In fineness, softness, length, and soundness of staple, and in colour, the Australian wools equal those of Germany; but they are in a bad state as to cleanness, though we believe that in this respect more care is evinced than formerly. If washed after shearing, they would arrive in sounder condition, and would command a higher price; but whether they would yield a larger profit, depends on the additional labour which, in the case supposed, it would be necessary to bestow. This is a point sometimes overlooked. Persons unaccustomed to reason upon facts connected with production are apt to think it must be better worth the producer's while to bring to market a good article, and so command a high price, than an inferior and therefore a low-priced article. But if to raise the value of his wool, say from 2s. to 2s. 6d., the New South Wales flock-master found it necessary to expend additional labour to the value of sevenpence, it is clear the advantage is on the side of the inferior wool.

In 1810 the importation of wool from Australia was only 167 lb., worth not above L.15. In 1820, the quantity had nearly reached 100,000 lbs.; and this year it will most likely exceed 12,000,000 lbs., being equal to our whole importation from every country in the world in 1810. The following is an account of the quantity of wool imported into this country from New South Wales and Van Diemen's Land from 1820 to 1839.

1820......	99,415	1830......	1,967,309
1821......	175,433	1831......	2,493,337
1822......	138,498	1832......	2,377,057
1823......	477,261	1833......	3,516,869
1824......	382,907	1834......	3,558,091
1825......	323,995	1835......	4,210,310
1826......	1,106,302	1836......	4,996,645
1827......	315,807	1837......	7,060,525
1828......	1,574,186	1838......	7,837,423
1829......	1,838,642	1839......	10,128,774

The great advantage of the growth of wool to a new colony like New South Wales is, that what really amounts to a large resource for her, forms but a small proportion of the whole quantity required in the market which she supplies. Thus the price of the article is not regulated by the cost of production, but by the state of the home-market. The local price may continue many years above the cost of production, and therefore give a great stimulus to supply; and yet the quantity may go on doubling in short periods, without reducing the price. This feature has been pointed out in the New Zealand Journal, a newspaper published in London, and devoted to the affairs of the colony which it represents; and also by the Westminster Review for December, in a paper on colonization.

" In the production of wool," says the writer in that review, " Australia enjoys an advantage which is somewhat analogous to the rent of the most fertile land in old countries. The demand of the consuming countries greatly exceeding the power of supply possessed by Australia, and no other country being able to produce so cheaply, the price is kept up to the European cost of production. Thus they enjoy a species of monopoly price. This has hitherto been the case with the cotton of America. It is now scarce sixty years since cotton was first exported from America, and this year the production is about 600,000,000 lbs. The following has been its progress in round numbers.

1790......	1,000,000	1820......	160,000,000
1800......	35,000,000	1830......	350,000,000
1810......	85,000,000	1840......	600,000,000

" The price of cotton, owing to the large demand created by our continually improving machinery, has generally exceeded the cost of production. This has generally stimulated production, and yet not so rapidly as the demand increased; hence the cotton of America has gone on displacing successive portions of eastern cotton, until the former now occupies all the channels of consumption; and so it will be with Australian wool. The consumption of foreign wool alone is in England 50,000,000 lbs. The greater portion of this will probably be displaced by the wool of the Australian colonies. In like manner, it will gradually cease to be worth while to raise sheep for their wool in many of the countries which now produce it.... With this increased facility of production," continues the reviewer, " it is not impossible that the manufacture of woollens will greatly increase in this country; that England will, in short, enjoy that pre-eminence which she now does in the case of the cotton manufacture, which she undoubtedly partly owes to the cultivation of the raw material in America."

Our importations from the Cape assume an important place in the following table. The average supply from the Cape during the four years ending with 1830 did not reach 30,000 lbs. annually. From that year a rapid increase has taken place; and if a better system of colonization were pursued at the Cape, so as to make the colony attractive to capitalists, the increase would be as marked as in the Australian colonies. The progress of our imports from the Cape is as follows.

1831.........	47,868	1835.........	191,624
1832.........	83,257	1836.........	331,972
1833.........	93,325	1837.........	468,611
1834.........	141,707	1838.........	422,506

Freedom of colonization and commerce is also operating beneficially with respect to the production of wool in the East Indies. In 1820, about 8000 lbs. were imported from thence; from that period to 1833 inclusive, the line in the official tables is blank. In 1834 the quantity imported was 67,763 lbs., in 1835 it was 295,848, and in 1838 it had increased to 1,897,266.

The South American States and Mexico, the importations from which, previously to 1833, were insignificant, seldom exceeding 200,000 lbs., now furnish considerable quantities.

In Europe also a quarter of a century of peace has produced very striking effects in the production of wool. Russia, which furnished but little previously to 1825, now supplies upwards of 4,000,000 lbs. From Italy, in like manner, we now import nearly as much as from Spain; while from insular and continental Greece and Turkey together we receive about 2,000,000 lbs.

With these necessary explanations, we submit to the reader the following table from the official returns, which is divided so as to exhibit the sources of supply in a conspicuous manner.

Table of the Importations of Wool in 1835 *and* 1838.

Country whence Imported.	1835.	1838.
Germany..................................	23,798,186	27,506,282
Russia....................................	4,024,740	3,769,102
Rest of northern Europe	1,157,345	1,063,074
Spain	1,602,752	1,814,877
Italy..	1,051,005	1,758,894
Greece	1,281,839	848,091
Rest of southern Europe	1,304,416	1,040,613
Northern Africa	816,625	511,426
Southern Africa	191,624	422,506
Rest of Africa	5,102	1,867
Australia	4,210,301	7,837,423
East Indies	295,848	1,897,266
Rest of Asia	... ...	... ...
South America and Mexico	2,195,400	4,059,958
North America	239,349	62,976
All countries..............................	42,194,532	52,594,355

The exportation of wool from this country is not extensive. We have for several years supplied Belgium with British wool, and France has been our customer for a small quantity. To the United States our export of wool is almost wholly foreign. The following table exhibits the total quantity exported for the years corresponding with the last table.

An Account of the British and Foreign Wool exported to the Countries specified, in the years 1835 *and* 1838.

Countries.	1835.	1838.
To Belgium....................	3,282,330	5,489,093
... France..........	2,034,695	2,003,047
... United States........................	3,209,424	144,679
... All other countries..................	217,855	112,381
All countries..............................	8,744,304	7,749,200

Thus, then, the result of our wool trade may be stated in round numbers as follows.

	Lbs.
Grown in the British isles	125,000,000
Imported[1]	50,000,000
Together	175,000,000
Exported	10,000,000
Manufactured	165,000,000

We conclude this part of our article with a statement of the prices of foreign and British wools at the end of June 1841.

		Per Lb.				
German, duty paid:

Goats' wool, Turkey		...			...	
Yarn, mohair		...			...	

The above prices are those of the qualities ordinarily to be found in the market. Occasionally some exceedingly fine samples are to be met with; they are called "fancy samples," and of course fetch fancy prices. We have now before us a sample of beautiful Saxon clothing wool of this kind, for which 7s. 6d. was paid by an extensive manufacturer of Leeds at a time that "Saxon first electoral was quoted at perhaps 5s. 6d." Such fancy wools being necessarily very limited in quantity, and being always readily bought, do not fluctuate much in price.

The origin of the manufacture of woollens is beyond the reach of tradition; but the keeping of sheep was among the prominent occupations of the oldest nations or tribes of which we have any record. It has been supposed that sheep and goats were originally kept for their milk, and the use of their skins for clothing could not fail to suggest itself to the rudest people. Indeed, among all savage tribes, even at the present day, we find the skins of beasts commonly employed for the above purpose; and among those barbarous nations a little advanced in intelligence, textile fabrics of various materials, and displaying more or less of ingenuity, are manufactured. The arts of spinning and weaving were known to and practised by the Egyptians; but the peculiarity of the woollen manufacture consists in the advantage which is therein taken of the felting property of wool. Pliny tells us that the art of fulling cloth was discovered by Nicias of Megara; but as Megara was founded only about 400 years before the building of Rome, or 1131 years before the Christian era, there is every reason to believe that the art was practised in the east long before his time.

Indeed the accidental matting of wool upon the sheep's back would naturally suggest the felting process. "Whilst the skins of sheep," observes Mr Luccock in his Treatise on Wool, "dressed with the wool on, served as clothing, it is obvious that only one useful fleece could be obtained from one animal; and as the fleece is generally cast or falls off once a year, this produce must have been wasted. In a very early period, however, the property which wool possesses of felting was discovered; or, in other words, it was found, that by pressure and moisture, the fibres of wool might be made to adhere together, and produce a compact pliable substance, quite as durable and more convenient than the skins formerly used. This appears to me to be the first effort to produce a woollen manufacture."

The art of spinning and weaving wool was known in the time of Moses, who wrote in 1450 B. C., or 320 years before the foundation of Megara; and as common use and exposure to weather would, to a certain extent, *full* an old garment, the fulling of cloth could not long remain unknown.

There is reason to believe that among the Romans the woollen manufacture had attained considerable perfection. We find among the Roman writers many passages drawing the distinction between the *piled* or *napped* fabrics and those which were simply woven, the threads being left exposed. The former were called *pexæ*, and the latter *tritæ*; and we may almost fancy that we discover in the distinction the difference between a fine cloth tunic and a common stuff garment.

From the very complete manner in which the Romans established themselves in Britain—resembling more our modern colonies, which have been described as "complete in all their parts," than our early American colonies, which were mere masses of labourers—we may infer that the woollen manufacture was introduced by them. Indeed Camden says they had a cloth manufactory at Winchester.

From the time of the Romans until the conquest we have no record of the manufacture of woollens; and even then the notices scattered among the writings of historians are exceedingly scanty. This however is certain, that among the Saxons, and indeed for many centuries after the conquest, the costume of the peasantry was of leather; and there is reason to believe that the "buff jerkin" retained its place as the ordinary dress of the labouring people of England until the time of the commonwealth.

It is generally supposed that the woollen manufacture was first introduced into this country in the reign of Edward III.; but though it increased considerably during that prince's reign, there is abundant evidence of its previous existence. Indeed Mr M'Culloch remarks,[1] that "there are notices in the statute-book of 'broad cloths two yards within the list,'[2] more than one hundred years before the date of the measures adopted by Edward III. for its improvement;" to which observation we may add, that scattered notices of the manufacture during most of the ten reigns preceding that of Edward III. are to be found.[3]

---

[1] Average of the last *four* years, 51,841,246.

It is stated by William of Malmesbury, that some Flemish weavers established themselves in the vicinity of Carlisle in the reign of William the Conqueror; but on some disagreement with the people in the reign of Henry I., they were afterwards removed to Pembrokeshire. In the same reign, cloth-weavers are mentioned in the exchequer accounts; and in the two following reigns they are represented as paying fines to the crown for the privilege of carrying on their trade.[4]

In the reign of Edward I. the office of aulnager of cloth was held for some time by one Peroult le Tayleur; but he having forfeited it, the office was conferred, by command of the king, on one Pierre de Edmonton, "if he were fit for it." These several facts prove the statement of Mr M'Culloch, that the manufacture existed; but beyond that we really know nothing.

In the fourth year of the reign of Edward III., John Kemp, a Flanders cloth-worker, received a license to establish himself in this country. Accordingly he settled, with a number of dyers and fullers, at Kendal in Westmoreland, where his name appears at this day. "Kendal Green" afterwards became celebrated, as every romance reader knows. It is mentioned by Shakspeare in his play of Henry IV.; and in the reign of Elizabeth the manufacture was in a most flourishing condition.

During the reign of Edward III. the manufacture seems to have spread itself all over the country. (Rymer's Fœdera, vol. i. 195.) Woollen fustians were made at Norwich, baizes at Sudbury, broad cloths in Kent, kerseys in Devon, friezes in Wales, cloths in Worcestershire, Gloucestershire, Hampshire, Sussex, and Berkshire, coarse cloths in the west riding of Yorkshire, and serges at Colchester in Essex and Taunton in Devon.

There was also during this reign, and indeed previously to it, much legislation in the mistaken spirit of interference so common in that age, and since unhappily continued by the operation of sinister interests, for the purpose of regulating the trade. On the plea of the superiority of English wool, the cloth-makers of London had been forbidden, as early as the reign of Henry II. (1185), to mix Spanish with native wools; but the circumstance at this distant day only proves two things: 1. that the wool of Spain, like that of Germany in modern times, is absolutely necessary for the production of cloth of good quality; and 2. that the class connected with the land were at least as powerful as they are at the present day.

The improvement of the cloth manufacture caused a diminution of the exportation of wool, and a duty was levied on the exportation of cloth. Various acts, which would now be deemed extremely vexatious, but which were then intended to protect the trade, were passed relative to the measurement and fulling of the cloth; and in the year 1357, Blackwell Hall was established by the mayor and common council of London as the cloth-market of the city.

In an exchequer record of the year 1355, published by Misselden in 1623, we find among the exports and imports the following records of the woollen trade.

Exports.—	Wool, 31,651½ sacks	L.189,909
	Felts, 3665 No.	6,073
	Cloth, 4774 cloths	9,549
	Worsted, 8061 pieces	6,718
Imports.—	Cloth, 1832 cloths	L.10,922

This statement is valuable, as shewing that, in the reign of Edward III. we imported fine cloths and exported coarse cloths, as their respective values in the above table shew.[5]

During the following reigns the same spirit of undue interference ran through the legislation of the period. In the reign of Henry IV. cloths were ordered to be stamped with a seal of lead. In that of Henry VI. cloth-searchers were appointed for every hundred throughout the kingdom, and the exportation of yarn was strictly prohibited. In the same reign we find evidences of the "reciprocity system," which has since been revived in the same narrow spirit. It was enacted, "that if our woollens were not received in Brabant, Holland, and Zealand, then the merchandise growing or wrought within the dominions of the duke of Bourgoine shall be prohibited in England, under pain of forfeiture;" and in the following reign the importation of woollens was prohibited. These several facts are chiefly valuable for the inferences which we may draw from them touching the growth of the woollen manufacture. The first-named act shews that, early in the fifteenth century, we were enabled to supply with woollens the very countries whence we derived the manufacture; and the last-named act affords evidence that the cloth manufactures in the latter part of the same century had become sufficiently powerful to turn the tide of bad legislation in their own favour.

We have seen that in the reign of Edward III. the high-priced cloths were imported, the manufactures of this country being of a coarser kind; which however were even then produced under sufficient advantage, considered relatively to other nations, to form a considerable article of export. In the reign of Henry VII. however a change had taken place; cloths of considerable fineness must have been produced, for we find that, in the fourth year of that monarch's reign, a maximum was fixed on the price of fine cloth: "every retailer of fine cloth who should sell a yard of the finest scarlet grained cloth above sixteen shillings" should forfeit 40s. a yard for the same. During this reign the "merchant adventurers," who dealt much in manufactures, selling the same to foreigners, became a powerful body.

In the following reign the woollen trade was generally in a most flourishing state, and the worsted manufacture especially increased rapidly. Some attempts were made by the crown, through the agency of Wolsey, to interfere with the freedom of the merchants; but we find these men entertaining more correct notions than their rulers. Wolsey is said to have threatened that the king would purchase of the manufacturers, open a new mart at Whitehall, and sell to the strangers; but the merchants told the cardinal, that the king might buy as well at Blackwell Hall, and that the strangers would gladlier receive their goods there than at Westminster. In this there is good political economy, and it does not appear that the king ever acted on his threat.

At this time one Jack of Newbury was deemed the greatest clothier in England. He was the owner of one hundred looms, and is said to have equipped as many men-at-arms for the Scottish wars at his own cost.

---

[1] M'Culloch's Statistical Account of the British Empire, vol. ii. p. 43.

[2] Henry III.

[3] We may here mention, once for all, that most of the facts respecting the early history of the woollen manufactures are taken from Smith's Memoirs of Wool, and the works to which he refers. Down to the year 1720, it is perhaps the most accurate record of the subject extant. It is extremely interesting, and is written in a spirit of liberality far beyond the age in which the author lived.

[4] Madox's History of the Exchequer.

[5] The pound sterling of Edward III. contained three times as much silver as at the present day.

York, at this time the next city to London in population and wealth, had long been deemed the great seat of the woollen trade in the northern counties. This branch of manufacture had established itself there in the reign of Edward III., and it seems steadily to have increased from that period. The trade also spread into other parts of the county, and we find many evidences that Halifax had grown into importance. The trade indeed prevailed in Halifax as early as 1414, but it does not appear to have increased until after the year 1443, when the advance was steady until 1540, during which period the number of houses is stated by Wright, in his History of Halifax, to have increased from thirteen to 520. They had even influence enough to procure acts of parliament in their favour, couched in the narrow spirit of the legislation of that day.

Acts of parliament for the regulation of the woollen trade now began to multiply, which, if they prove nothing else, prove the importance which the staple trade had at this time assumed. In the reign of Edward VI. Coventry and Manchester are named as the seats of manufacture; and in that of Philip and Mary a long act was passed regulating the making of woollen cloths, and confining the same to market-towns. Ten or eleven counties, besides North and South Wales, were excepted in the act; but it was deemed so oppressive that it was amended in the first year of the next reign.

At this time it should be observed, that the freedom of trade and industry was wholly unknown. Guilds or corporate bodies monopolized every trade or calling; and even the whole export trade of England was in the hands of three companies, the merchants of the staple, the merchant adventurers, and the merchants of the steelyard, the latter of whom were foreigners. In 1551 the merchants of the steelyard exported 44,000 cloths; and shortly afterwards the merchant adventurers, into whose hands this branch of trade fell, exported 100,000 cloths. The exportation of wool had been for some time diminishing, and we were rapidly becoming a manufacturing nation. Acts indicative of the ignorance which prevailed continued to be passed; but although the state sought to regulate every thing, our manufactures and trade grew in spite of vicious legislation. Some counties and towns, however, were relieved from the oppressive acts of former reigns, and a considerable number of foreign artisans settled in England; but generally the character of legislation was bad, and was indeed only tolerable because that of other countries was either equally bad or worse. The exportation of sheep was prohibited "for divers good causes and considerations;" and in the following reign the export of "white cloths" was prohibited, in order to give a boon to our dyers; but other countries adopted the same narrow policy, and by prohibiting the importation of British dyed cloths, defeated the intended monopoly. The woollen manufacture now declined apace, and the persecutions and civil disorder during the contest with the Stewarts, that is, from 1620 to 1688, almost annihilated the trade. The exportation of wool was alternately prohibited and permitted, according to the notions of the government. The great prosperity of the woollen trade in Elizabeth's reign had been coincident with free trade; but as ignorance prevailed throughout all classes, vain attempts to secure monopolies found favour with the public, notwithstanding repeated failures. Oppressions drove the manufacturers out of the kingdom; and it is said that two thousand left the country at one time under Thomas Pelham of Warwick, and shortly after more joined them. This was in the year 1665, when the white clothing trade had fallen off from 100,000 cloths to 11,000, without any increase in the exportation of dyed cloths.

The legislation of the commonwealth was just as unwise as that of the Stewarts. The exportation of wool, fullers' earth, and all the materials of manufacture, was prevented, and it seems never to have entered the minds of the promoters and framers of these laws that other nations could produce these articles; nor was it until about the year 1660 that the superiority of Spanish clothing wool was admitted, when our manufacturers began to mix it with English wool, to the great improvement of the cloth.

To enumerate the various schemes to remedy the depressed state of the woollen manufacture about this period, would occupy more space than we can afford. They will however be found in Smith's Memoirs of Wool, a work to which we are much indebted. Suffice it to say, that bad legislation continued its work until it had paralyzed the trade.

In the mean time the woollen manufacture found its way into Ireland. Some English clothiers had settled at Dublin, Cork, and Kinsale, and a more considerable establishment was formed at Clonmel. Some Frenchmen also set up a manufacture of druggets at Waterford, and the success of these excited the jealousy of the English clothiers, who ascribed the depression of the trade to Irish competition. The farmer also attributed part of his distress to the importation of Irish wools; and, with singular inconsistency, the clandestine export of both English and Irish wools was deemed the cause of the increase of foreign manufactures. These erroneous notions produced another crop of bad legislation, and the result was, that the very evils complained of were actually produced. Nearly all the tracts on trade published at that time, and nearly all of which are briefly noticed in Smith's Memoirs of Wool, will be found harping on the declining state of trade, and recommending measures calculated to produce the worst of evils. The great complaint was "the running of wool;" and although the consumption of Spanish wool was annually increasing, because its merits were becoming known, manufacturers, traders, legislators, all seemed to act under an impression that no wool in the world equalled that of Great Britain.

As the consumption of Spanish wool increased, English cloth improved; and, immediately before the Revolution, our manufacturers opposed with some success the rivalry of the French, which had become extremely injurious to British manufactures.

The tranquillity produced by the establishment of the princess Mary and the prince of Orange on the throne was extremely favourable to the woollen manufacturers, more especially as many of them were Protestant dissenters, who had not enjoyed under the domination of the Stewarts that degree of religious liberty which they craved. Towards the end of the century, it was calculated that the total woollens manufactured in this country amounted to L.8,000,000, of which about L.2,000,000 were exported. From 1718 to 1722 it averaged L.3,000,000. For the ten years ending with 1748 the number was L.3,300,000; and for the following five years L.4,200,000, from which time the advance has been progressive down to the present time.

The principal seats of the woollen manufacture are the western counties and the west riding of Yorkshire. From the year 1726 until the year 1821 accounts were kept of the quantity of cloth manufactured in the west riding of Yorkshire, as exhibited by the returns from the several fulling mills made at the Easter quarter-sessions held at Pontefract. The table for every year of the period will be found in Marshall's Statistical Tables; but for the purpose of bringing the progressive increase of the manufacture before the eye of the reader, apart from all occasional and temporary fluctuations, we have arranged the last fifty years of the table in five periods, giving the total and averages for each period.

Statement of the Number of Pieces and Yards of Broad and Narrow Cloth milled in the West Riding of Yorkshire from 1772 *to* 1821, *divided into Periods of Ten Years, showing the Totals and Averages during each Period.*

Ten Years ending with the Year specified.		Broads.		Narrows.		Both.	
		Pieces.	Yards.	Pieces.	Yards.	Pieces.	Yards.
1781......	Total..................	1,063,268	31,542,322	946,704	24,997,158	2,009,972	56,539,480

The only account we have of the quantity manufactured in the west of England, is the following official table of the manufactures of Gloucestershire, taken from the Assistant Hand-Loom Commissioners' Report of that district.

A Return of the Number of Yards of Woollen Cloth made in Gloucestershire in each Year from 1822 *to* 1838 *inclusive, so far as it can be supplied by the Records of the Excise Department.*

Years.	Broad Cloth, in Yards.	Narrow Cloth, in Yards.	Broad and Narrow Cloth, the kinds not being kept distinct.	Cassimere, in Yards.	Felt, in Yards.	Spanish Stripe, in Yards.	Pounds of Wool.	Pounds of Worsted.	Dozens of Hose.
1822	356,743	34,081	316,755	13,258	13,113	10,720	11,334	50	5,090

The broad and narrow cloths of the west riding of York do not comprise much more than one fourth of the woollen and worsted goods produced in that county. They are for the most part the produce of the clothing townships around Leeds, and in part of the villages in the neighbourhood of Huddersfield and Halifax; but they exclude the blankets and heavy woollens of Dewsbury and its neighbourhood, the worsteds of Bradford and Halifax, the "fancy cloths" of Huddersfield and Halifax, and the flannels and baizes of the district of Saddleworth, which have their market at Rochdale in Lancashire. In the neighbourhood of Skipton and Addingham are produced those worsteds which contain a mixture of cotton.

The west of England still enjoys its pre-eminence in the manufacture of superfine cloths, besides which serges, blankets, and flannels, are there produced. Woollen cloths are made principally at Frome, Ilminster, Twerton, and Chard in Somersetshire; at Stroud, Wootton, Chalford, Dursley, Nailsworth, and Stonehouse, in Gloucestershire; at Bradford, Heytesbury, Melksham, Chippenham, Calne, Wilton, in Wiltshire; at Lyme Regis, Up-Lyme, and Dorchester, in Dorsetshire. Kidderminster in Worcestershire is the seat of the carpet manufacture of the west of England; Salisbury and Cullompton of the celebrated Salisbury flannels; Wellington in Somersetshire, and almost every village in Devon, produce serges; Witney in Oxfordshire still manufactures blankets to a considerable extent, and North Wales still sustains its reputation for superior flannels; but in point of cheapness the west of England has been for years giving way to the west riding of York, though the latter owes a considerable portion of its trade as much to its proximity to Liverpool, the great shipping port of the trade of the western world, as to any circumstance more immediately connected with production.

The west of Scotland has long carried on the manufacture of such woollen fabrics as were formerly peculiar to the country; but of late years the manufactures of other articles, such as blankets and fine and coarse broad cloths, have established themselves there with great success. The woollen goods now produced in the south-west of Scotland are, carpets, fine and coarse cloths, blankets, fancy trouser-pieces, tartans, shepherds' plaids, shawls of various kinds, and mousselines de laine.

Numerous estimates have been attempted of the number of persons employed in the woollen and worsted manufactures of Great Britain, or rather of the proportion of the population supported thereby; but as the data afforded by official returns for making even an approximate estimate are exceedingly imperfect, no reliance upon them can possibly be claimed. There is a note to Marshall's Statistical Tables, noticing many of the errors which have been committed; but he has himself not escaped errors. He says, "the first Lord Ellenborough, in his place in parliament, once stated that there were upwards of 3,000,000 of persons engaged in and dependent on the woollen manufacture. The Edinburgh Review more recently asserted that there were upwards of 1,000,000 so occupied and dependent. From the statement below his own table, it will been to be doubtful whether, in all its varied operations, more than 250,000, certainly not 300,000, persons are engaged in or dependent on that branch of industry." (P. 3.) This statement to which Mr Marshall alludes, was made by Mr Law, afterwards Lord Ellenborough, in 1800, when engaged as counsel for the petitioners against the exportation of wool to Ireland. He said there were 1,500,000 persons immediately employed, and that 3,000,000 were collaterally employed; meaning thereby to include machine-makers, carriers, and so forth. No doubt he was then wrong; but at the present day we cannot think the number short of 1,000,000, and when the census of the present year is made, it will be probably found to exceed it. Indeed Mr Marshall's own table shows a much greater number. He takes the several counties, and separates the agricultural, mining, and manufacturing, from each other. Thus, in the west riding he gives,—coal and iron, 13,997 families; agriculture, 15,331; manufactures, 85,096; all others, 17,767; making the manufacturing families about two thirds of the whole. Now these are nearly all engaged in the woollen trade, for those engaged in the cotton manufacture will be compensated by at least an equal number in Lancashire engaged in the manufacture of baizes, flannels, &c. In like manner, the manufactures other than woollen are insignificant, and will be compensated by woollens manufactured elsewhere. His table then will stand as follows:

West riding of York	85,096
West of England woollen districts	20,851
Norwich and Kendal mixed stuffs	17,570
Leicester North Derby hosiery, half worsted	20,464
Families	143,981

The proper multiple to count families into population is $5\frac{1}{3}$; that is, Great Britain in 1831 contained, in round numbers, 3,000,000 families, and 16,000,000 individuals. Hence 143,981 families = 766,899 persons. This does not include the flannel manufacturers of North Wales, the blanket manufacturers of Oxfordshire, and some scattered manufactures in other districts, for which an allowance of 20,000 families is not excessive. We shall then have 163,981 families, and 874,565 persons, directly supported by the woollen manufacture in England and Wales. We have no means of separating the woollen manufactures of Scotland from those engaged in other branches; but we find from the Report of the Assistant Hand-Loom Commissioners for Scotland, that the woollen trade is carried on to a considerable extent in the shires of Lanark, Renfrew, and Ayr; and also, though not so largely, in Dumfries, Roxburgh, Selkirk, Edinburgh, and slightly in Peebles and Bute. We are disposed to estimate the woollen trade somewhere between a fourth and a fifth of that of England. The climate being more severe, there is a much more constant use of woollen among the people than in England. The shepherd's plaid takes the place of the linen smock-frock of the south, so that the extent of the manufacture must not be judged by the quantity exported. However, to be on the safe side, we will fix it at one fifth of that of England, or 32,800 families, or 174,933 people, dependent on the woollen manufacture, which, added to our previous number, gives 196,781 families, and 1,059,495 people.

But it must be further observed, that this calculation is based on the population returns of 1831, since which time our population, manufactures, and trade, have greatly increased. Between 1821 and 1831, the increase for the whole kingdom was $15\frac{1}{2}$ per cent.; and since then, from improvements in agriculture, and generally productive harvests, it is generally thought that the ratio of increase will be found to be greater. The increase of the manufacturing districts generally was much greater, for the most part exceeding twenty per cent. With the moderate addition of fifteen per cent. for the increase of the woollen manufacture in 1841, as compared with 1831, we have 226,298 families, consisting of 1,218,424 persons, dependent on the woollen manufacture for their subsistence.[1] When we consider that our manufactures employ 1,350,239 families, and that the woollen manufacture requires a greater number of manual operations than any other, we are inclined to think our estimate within the truth.

Although the quantity produced, and amount of capital employed, in the manufacture, is a subject of difficulty, and all calculations are mere approximations, more or less remote, according to the care with which the calculations were made, the quantity exported is more accurately ascertained; and the following table conveys the most recent account published.

An Account of the Quantity of Woollen Manufactures exported in the year 1838, *shewing the Country to which each Article was sent.*

Countries.	Woollen Yarn.	Cloths of all Sorts.	Napped Coatings, Duffles, &c.	Kerseymeres.	Baizes of all Sorts.	Stuffs Woollen or Worsted.	Flannels.	Blankets and Blanketing.	Carpets and Carpeting.	Woollens Mixed with Cotton.	Hosiery. Stockings, Woollen or Worsted.		Sundries, Coverlids, Rugs, Tapes, and Small Wares.	Declared Value of Woollen Goods.

---

[1] Mr M'Culloch, in his Statistical Account of the British Empire, estimates the number of people employed in 1826 at 334,000. This is not inconsistent with our estimate of 226,298 families in 1841.

An Account of the Woollen Manufactures exported from Great Britain, distinguishing each Description of Goods, from 1820 *to* 1838.

In 1815, Mr Stevenson estimated the whole value of the woollen manufactures of Great Britain at L.18,000,000, and the number of people actually employed at 500,000. Mr M'Culloch estimates the value in 1827 at L.22,500,000, on the supposition that the manufactured article is worth three times the value of the wool, the quantity of which he estimated at 490,000 packs English, or 117,600,000 lbs.; and 30,000,000 imported, a quantity far within the present amount. Our calculation proceeds on the basis of 226,298 families, earning on an average 17s. 6d. per family, and allowing a consumption of wool worth L.10,000,000, with an allowance of twenty-five per cent. on all outlay for wear and tear, interest, and profit of capital. We then have the following estimate:

Value of wool employed	L.10,000,000
Oil, dye-stuffs, soap, &c.	1,500,000
Wages	10,296,559
Wear and tear, profits, &c.	4,359,311
	L.26,155,870

We now come to describe the manufacture of the wool of the sheep in its two great divisions of woollen and worsted manufacture. Before we enter fully into the two processes, it may be well to indicate in what the difference consists. We have already described that peculiar property of wool called the felting property, by which the fibres, when submitted to heat, moisture, and pressure combined, form one almost homogeneous mass. Of this property advantage is taken in almost every article of woollen manufacture, the yarn being softly and loosely spun for the purpose. In the case of worsted, on the other hand, the felting property is neglected, the wool is submitted to the process of combing, which rather impairs, though it does not destroy, the felting property; and the fibres being elongated and laid even, the thread is twisted and spun hard, so as to feel close, hard, and thread-like to the touch, and not soft and loose like the yarn destined for the manufacture of woollen cloths. Keeping this distinction in view, we will first treat of the manufacture of cloths, the most perfect of woollen fabrics; and the following is a catalogue of the processes, which we shall describe *seriatim*.

1. Sorting the wool.
2. Scouring or washing.
3. Dying (when wool-dyed).
4. Willying or twillying.*
5. Picking or moating.
6. Oiling.
7. Scribbling.*
8. Carding.*
9. Slubbing.*
10. Spinning.*
11. Reeling.*
12. Warping, patenting.
13. Sizing.*
14. Weaving.*
15. Scouring.
16. Dying (when piece-dyed).
17. Burling.
18. Fulling or felting.*
19. Scouring.
20. Drying (tentering).
21. Raising, dressing, or teazling.*
22. Shearing or cutting.*
23. Brushing.*
24. Picking, drawing, and marking.
25. Pressing.*
26. Packing.

* These processes are performed by machines.

The sorting of the wool, and the *tact* or delicacy of hand and nice discrimination which it requires, have been described in the first division of this article. The sorter is usually attended by a boy to distribute the sorts: so attended, a skilful sorter can sort a pack of German wool in about two days, and a pack of English in one. The wages which a sorter is capable of earning vary from 25s. to L.2, L.2. 10s., and even L.3; but the latter demands a union of skill and rapidity seldom attained.

The proper sort having been selected, the wool is scoured or washed, to free it from the animal grease with which it abounds. This in the west of England invariably, and in Yorkshire generally, is effected as follows. Stale urine, called in the west of England "ley," is mixed with a small quantity of soap, and heated to about 120°. In this detergent the wool is soaked. On removal, it is placed in a wire basket, and submitted to the operation of running water, by which the grease and other impurities are washed away. By some manufacturers of Yorkshire, the wool is washed with warm soap and water, and, after receiving a second washing in clean water, to free it from the soap, is passed through strong iron rollers, by which the wool is pressed nearly dry. The business of scouring or washing is performed by men; and by the first process, two are capable of cleaning two packs in a day.

Cloth, other than white cloth, is either "wool-dyed" or "piece-dyed." Of the former, the dyeing is the first process after washing. The larger manufacturers themselves dye all the common colours, such as browns and olives; but the true or woaded colours, such as blue, wool-black, and green, can only be well done by those who make it their special business. The small manufacturers send all colours to the dyers. The prices paid for dyeing vary, ac-

Wool, and its Manufactures.

cording to the colours, from 10d. to 1s. 6d. per lb.; that is 10d. to 1s. for woaded medleys, 1s. to 1s. 2d. for wool-dyed blacks, and 1s. 2d. to 1s. 6d. for blues. Piece-dyed cloths are sent to the dyeing-house after fulling and scouring (see DYEING).

Delivered at the mill:—the wool (dyed or undyed, as the case may be) is now submitted to the first of a series of machines, all of them admirably adapted to perform their respective parts in the production of the woven fabric. This first machine is called the willy or the shakewilly in Yorkshire, and the twilly in Gloucestershire. Both seem to be a corrupt mode of pronouncing the willow of the cotton manufacture (as the Scotish call window windy); and even willow is probably a corruption of winnow, *winnowing* the wool being really the office it performs.

There are various kinds of willying machines in use, but the best appears to be the conical willy, made by Mr Lilly of Manchester. It was first applied to the cleansing of cotton; but it has been tried in Leeds with success, and, we believe, is now used to a considerable extent.

The willy consists of a revolving cone, armed with four rows of iron spikes, strongly fixed to four longitudinal bars, which being fastened to three concentric wheels of different diameters, the common axis of which forms the shaft of the machine, the conical form thereof is at once accounted for. This cone revolves at the rate of from 300 to 500 revolutions per minute, within a casing cylinder, armed with similar spikes, but placed so as to alternate with the spikes on the cone. At the small end of the cone is a eccentric covering of thin sheet-iron, and at the large end is a gridiron plate.

The machine is fed by means of an endless apron, the wool entering at the smaller end, so that when most entangled it is subjected to the least motion. This apron is a great improvement on former machines, which were filled by hand; an operation attended with danger, and sometimes resulting in accidents. By the revolutions of the cylinder, the wool is torn, disentangled, and cleansed; and by the gradually increasing centrifugal force, it is impelled forwards towards the large end of the cone, encountering in its way increased motion; which, however, it is the better able to bear, by becoming less and less entangled at every revolution.

When the wool thus reaches the base of the cone, it is tossed into a chamber, where it is received upon another endless apron, moving in a direction from the machine instead of towards it. Over this apron is a cylindrical wire cage, which revolves on an axis disposed parallel to the apron, and immediately over it a revolving fan. Both these are covered and protected by sheet-iron casings, but communicate with the chamber which receives the wool from the cone. When the whole is at work, the fan, drawing the dust out of the chamber, blows it through a chimney or pipe, connected with the machine for the purpose. The cage prevents the escape of the wool with the dust, and by its passage over the apron it lays down the wool in a continuous fleece.

The coarser wools, destined for common cloths, are willied more than once; for instance, before as well as after dyeing, and after oiling and before being scribbled. The finer wools do not however require this, as the operation of scribbling is a sufficient preparation for carding.

In the west of England the wool is beaten with wooden rollers by women, after which it is placed on a wire screen or hurdle, and pulled with the hands, so as to get rid of any burs, or pitch, or other dirt which may not have been separated by the willy. In Yorkshire the wool is picked by a boy, called a wool-moater. If this be not done, the scribbling machine is injured by any lumps of pitch so frequently found in wool.

The wool is next oiled for the scribbling machine, three or four pounds of Gallipoli oil being intimately mingled with twenty pounds of wool. A man can oil about twenty score, that is, 400 lbs., in a day.

The process of scribbling differs but little from that of carding; the only difference being that the machine is coarser, and that the wool is delivered in a continuous fleece instead of narrow bands or slivers. The object of both is further to separate and open out the fibre of the wool, and even to tear it asunder. Both processes should, if successfully performed, equalize the quantity of wool in a given length of cardings. In order that the disentangling and separating of the wool may be as complete as possible before it is moved from the scribbling to the carding engine, it is sometimes made to undergo the scribbling process two or even three times.

In Plate CLXXVII. (COTTON MANUFACTURE) figs. 1, 2, 3, and 4, the carding engine used in the cotton manufacture is shown; but the wool-carding engine is somewhat different, as it consists of one large cylinder or card-drum, surmounted by three pairs of smaller cylinders, called urchins, all of them covered with card-cloths armed with carding wires. The smaller cylinders are of unequal size. The larger of the two is called the *worker*, and the smaller the *cleaner*, which revolves at great speed. At one end of the engine is an endless feeding apron, upon which equal portions, by weight, of the oiled wool is evenly spread by hand. This apron, by its motion *towards* the engine, delivers the wool through a pair of *feed-rollers*, which distribute it upon the card-drum. From this the wool is gradually stripped, as it were fibre by fibre, by the first worker, whence it is received by the first cleaner, and by it again deposited in the card-drum. This is twice repeated, so that the disentanglement and separation of the fibre becomes more and more complete. When it has passed over the last cylinder on to the drum, it is taken from it by a cylinder somewhat larger than the workers, and called a doffer; from which again the wool is scraped off by a *doffing knife*, which moves rapidly up and down by means of a crank, so that it scrapes the doffer downwards only. In the scribbling process, the wool is wound round a revolving roller, in an endless fleece, having the appearance of a fine blanket. But the carding engines differ from the scribbling machines in the mode in which the doffer is armed, and in the contrivance for receiving the wool from the doffer. The doffer, instead of being uniformly covered with wires, is merely armed with a succession of card-leathers, arranged in longitudinal bands parallel with the axis of the doffer. The effect of this is, that the doffing-knife detaches the wool from the doffer, in the shape of bands or slivers. These, instead of being wound round a roller, fall into the flutes of a fluted cylinder; and as half of this cylinder is covered with a case, called a shell, near enough to the cylinder to touch the slivers as they lie in the flutes or grooves, they are rolled into what are called *cardings*, and are received upon an apron moving in a direction *from* the engine.

The several cylinders move at different velocities, not merely in relation to their surface, but in the relative number of revolutions which they perform in a given time. The card-drum is usually three feet in diameter, and makes one hundred revolutions in a minute. The workers are about eight inches in diameter, and make only ten revolutions in a minute; hence the surface of the drum moves forty-five times as fast as the workers. Their surfaces move in the same direction.

The cleaners revolve in the contrary direction, and they card the wool on the drum as well as on the workers. They move very rapidly, namely, 300 revolutions in a minute; but as they are only one ninth of the diameter of the drum, their surface has only one third of the velocity of the surface of the drum.

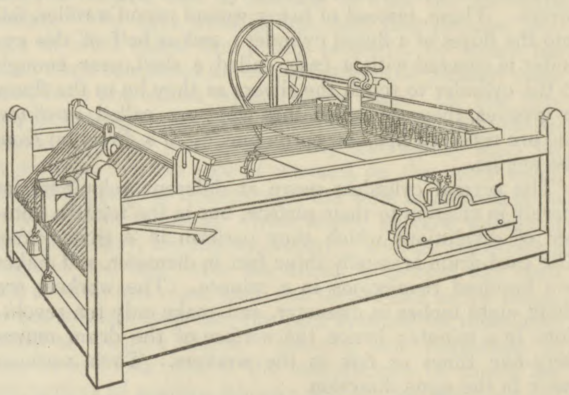
The worker next the doffers is called the fly, from its great velocity. It is furnished with straight teeth, and it does not take the fibres from the card-drum, but merely raises them to the surface, from which they are stripped by the doffer, the surface velocity of which is only one thirtieth of that of the drum. The wool is then scraped off by the doffing-knife, and rolled into cardings, as already described.

These several processes come under the general term *preparing*. Within the last year, a patent has been taken out by Mr Thomas Walker of Galashiels, for an improved mode of feeding the preparing machinery, which is said to produce a more even yarn than the old methods.

After the wool is thus prepared by the operations of willying, scribbling, and carding, it is in a state to be spun into yarn by machines, which elongate the cardings, rovings, or rollers as they are called in some districts, and at the same time twist them in the required degree. The process of spinning, and the recent improvements in the machinery employed in it, have been carefully described in the articles COTTON MANUFACTURE and SPINNING; and all that now remains is to describe the mode of spinning yarn proper for the manufacture of woollen cloth. This is effected in two operations. The first, called slubbing, is performed with a machine called a slubbing billy, which is certainly behind the generally improved state of manufacturing machinery; and the second and more complete spinning is effected either with the jenny or the mule.

In the operation of slubbing, the cardings are joined together end to end, elongated to a certain extent, and slightly twisted to give them sufficient cohesion and strength. The "slubbing" thus produced has the appearance of a soft and weak thread.

The annexed figure will give a clear conception of the slubbing billy and its mode of operation. The spindles are arranged on a moveable carriage, which runs along the frame of the billy on friction wheels. The cardings are arranged on an endless apron, in a slanting direction, at the end of the frame, opposite to the carriage. They then pass under a wooden roller, which presses lightly upon them, so as slightly to compress them. In front of this roller will be seen a moveable rail, which, when it rests upon the cardings, prevents their being drawn through the rollers, but when elevated by means of the lever seen underneath, prevents the cardings from being drawn forward by the retiring of the spindle carriage. Immediately over the spindles, it will be observed, is a wire, which, when let down upon the yarns, presses them downwards, and allows them to be wound round the spindles by their revolutions, as the carriage is moved home by the slubber.



We will now suppose the carriage to be at rest, not as seen in the figure, but close to the rail and roller above described. A small wheel on the carriage, by passing under the levers (seen under the roller and rail), elevates the rail, and permits the cardings to be drawn freely through the roller the moment the slubber moves the carriage towards the extremity of the machine. The cardings are brought from the carding engines by children, and, by a slight lateral rolling motion of the fingers, are joined on to the ends of the cardings already attached to the machine. This is repeated as often as necessary. In order to prevent the undue thickening of the cardings at the junction, each carding is smaller at the ends; and some little tact is required on the part of the piecers, or pieceners, as the children who perform this work are called, to prevent any inequality at the junction. This tact is soon acquired, even by very young children.

The slubber now seizes the rail of the carriage, and draws it slowly out. As the rail in front of the slubbing roller is elevated by the upward pressure of the lever, the carding is drawn through, without being elongated, about eight inches. At this point the lever is disengaged, and the rail descends upon the cardings and pinches them fast. As no more can be drawn out, the further drawing back of the carriage necessarily elongates the cardings, and by the motion of the spindles a slight twist is at the same time given to them. This is effected by the slubber turning the wheel with his right hand, his left being occupied with the carriage-rail; and the handle, as will be seen, is brought within his reach for the purpose.

It should be observed, that during this part of the operation, from the inclined position of the spindles, the yarn is not wound round them by their revolution, but at every turn it slips off, being merely twisted by the revolutions of the spindles. When the slubber judges the yarn to be sufficiently twisted, he moves the carriage forward, and at the same time brings the *faller-wire* down upon the whole row of yarns; then, by setting the spindles in position, the yarns are wound round them in the form of a double cone. The faller-wire is connected with the carriage-rail by two arms; and as the rail turns on its axis, the slubber is able to raise or depress the wire as he grasps the rail to move the carriage forward, by the motion of his wrist.

The billy, like the jenny, has generally sixty spindles. One carding engine will keep one billy employed, and, with steady work, one slubber should have four pieceners, who consequently have each fifteen cardings to manage. There is no excessive labour in the operation, nor is the attention of the children painfully overstretched; but the evidence given before the Factory Commissioners shews that the children were subject to much cruelty from the slubbers, who are often irregular and intemperate, making up for lost hours by excessive work, and beating the children who work under them for the slightest fault. Dr Ure mentions an invention by Mr Charles Wilson, intended to supersede the slubbing billy in preparing the wool for spinning. It consists of an adaptation of a system of rollers to the carding machine, by which the cardings are sufficiently elongated for the operations of the mule or the jenny. We are not aware that this machine has come into use: if so, it has not been our fortune to meet with it, though our acquaintance with the clothing districts of the west riding of Yorkshire is extensive.

The whole history of the great inventions by which the art of spinning has arrived at its present state of perfection has been already given in the articles COTTON MANUFACTURE and SPINNING. The jenny is still used to some extent in Yorkshire, though the mule is fast superseding it. In some of the clothing villages of the west riding, it is the custom of the manufacturers to give out the work in slubbing, and the workman spins and weaves at so much per string of ten feet. In other places the small manufacturers, who have perhaps two, four, or six looms, purchase the wool, and get it scribbled, carded, and slubbed at a mill, then spin and weave it themselves, and after getting it fulled at the mill, carry it to the Leeds cloth-market in an unfinished state. In both these cases the jenny is made use of. These mills are not unfrequently built by subscription by the small manufacturers. A manager is appointed, the regular price for slubbing, &c., is charged, and the profits are divided at the end of the year. In the larger manufactories at Leeds, the mule is used instead of the jenny. In some of these factories all the operations from sorting the wool to packing the cloth are carried on, whilst in some the weaving is given out. The establishment of Messrs Hirst, Bramley, and Co. is a sample of an admirably regulated factory, where the whole process of cloth-making is carried on; and we are much indebted to those gentlemen for the facilities afforded us in the prosecution of our inquiries. To Messrs Ripley and Ogle we are also similarly indebted.

The operations of warping and weaving, and indeed every thing connected with them, have been fully described in the article Weaving: all that we need mention here is, that the hand-loom is chiefly employed at present, though there seems every probability that Messrs Sharpe and Roberts's improved power-loom will rapidly supersede the hand-loom. In several factories of Leeds, power-looms are employed to weave the finest and broadest cloths, namely, such as are twelve quarters wide in the loom; and we could discover no greater difficulty than in the weaving of worsted stuffs, to which power has been extensively applied.

The cloth is woven of the width just mentioned, to allow for the shrinking which it undergoes by the processes of scouring and fulling, especially the latter. The outer edges of the cloth have a list border, which receives the tenter-hooks in stretching. This list in the west of England is made of goats' hair, but in Yorkshire it is merely formed of coarse yarn. This, we believe, is all that is necessary to be added to what will be found in the article Weaving.

After the cloth comes from the loom, and before it can undergo any other process, it is necessary to scour it, in order to get rid of the oil and size to which the wool and yarn have been subjected in the preparatory processes. This is performed at the mill, in a somewhat rude machine, called the stocks, and consisting of a pair of wooden mallets, worked alternately by a cog-wheel. The cloth is exposed to the stroke of the mallet in an inclined trough, the end of which is curved, so that the tendency of the stroke is to turn the cloth round and round, and different portions are alternately exposed to the operation of the hammers. At first soap or some other detergent is used, but at last a stream of pure water is let in upon it.

It is now carried to the drying room or tenter-ground, and stretched upon a vertical rail or tenter-hooks, where it is left to dry in the extended state. The lower rail of the tenter-frame is made to slide, so that the cloth may acquire the requisite degree of tension.

The cloth thus cleansed and dried is delivered over to the burlers, who pick out all irregular threads, hairs, or dirt of whatever kind, which may remain in the fabric. This process is called burling, and to perform it, the cloth is examined both on the surface and through the web against a strong light. In the larger factories a room is assigned to the business of burling; but in the cloth-villages of the west riding, during the summer months, the process is carried on by the wayside and in lanes, on walls and on hedges.

The cloth is now ready for the operation of the fulling-mill, which, like the scouring stocks, is furnished with mallets driven by a cog-wheel; but the milling trough has a square instead of a circular end, so that the cloth receives the direct blow of the mallets, and is not made to escape from the blow by the operation itself. The stroke of the mallets is extremely heavy, but it does not injure the cloth, on account of the multitude of folds. This greater force, as compared with the scouring stocks, is produced by the hanging of the hammers. The shafts of the scouring stocks are nearer to the perpendicular, so as to cause the mallets to move more horizontally, and therefore with less velocity. They are hence called *hanging* stocks, while those of the fulling-mill are called *fulling* stocks.

Improvement has of late found its way into this branch of the cloth-manufacture as well as into others. The old fulling-mill was of wood; but such machines are now constructed of iron, with much more accuracy, and work with greater precision. The best of these is the invention of Messrs Willans and Ogle of Leeds. The bed of this machine is hollow, so as to form a steam-chest, connected by a pipe with a boiler, so as to keep up the degree of heat necessary to the perfection of the fulling or felting process. But the great improvement of this machine is a contrivance for altering the form of the trough against which the cloth receives the stroke of the mallet. This consists of a moveable curved plate, traversing on a fixed hinge-rod at the bottom of the trough. The upper edge of this curved plate is capable of being advanced towards or withdrawn from the mallets, by means of a screw-rod attached to its back. By this means the directness, and therefore the force, of the stroke is altered so as to suit the different qualities of cloth.

To the felting property of wool we have already alluded. By the united operations of beating, heat, and moisture, the minutely jagged surfaces of the fibres of the wool are made intimately to cohere, and form not a mere woven tissue like cotton, flax, or silk, but a felted homogeneous mass, similar to the paper on which we print. If a piece of cloth be cut it will not unravel, the tissue is almost lost under the thick fulled surface raised upon it, and the weaving seems less to give a character to the fabric than to impart the requisite degree of strength.[1] Superfine cloths have four fullings of three hours each, a thick solution of soap being spread between each layer of cloth every time. Scouring is aided by fuller's earth, that which is found in England being said to be superior to any other.[2] Rinsing with clear water completes the process, which diminishes the width of the cloth between forty and forty-five per cent., and the length about fifty per cent. After every impurity is washed out, the cloth is again stretched upon the tenters until it is completely dry.

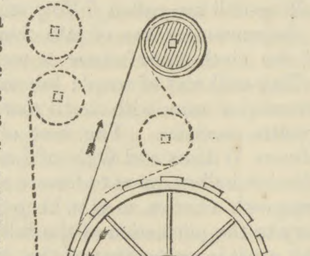
The cloth next undergoes the operation of teazling, by which the loose fibres of the wool are raised to the surface, so as to form, when duly cut or sheared, the pile or nap. For this purpose the teazle, a species of thistle (*dipsacus fullorum*) is employed. This useful plant is cultivated in the clothing countries, and especially in Somersetshire, where they are sold in packs of 20,000, at about L.6 per pack. In periods of scarcity the price has advanced as high as L.22 per pack, followed by a great importation from France, and a consequent glut, reducing the price to L.3. A piece of forty yards consumes 3000. This state of circumstances has induced many to turn their attention to the invention of some metallic substitute, but the thistle teazle still maintains its supremacy.

Formerly the teazle was fixed in a hand frame, and worked by two men in the manner of a large two-handled brush or hand-card; but for many years the gig-mill has been employed, in which the teazles are arranged in a cylinder, and the cloth being stretched on two cloth-beams, one above and one below the teazle cylinder, the cloth moving in a direction contrary to its revolutions, its surface is exposed to the operation of the teazles. In the older gig-mills, the cylinder was completely bristled with the teazles; but in the modern mills they are arranged in longitudinal frames parallel to the axis of the cylinder, with equal spaces between each, like the bars of an immense reel. The mode in which the cloth is stretched on the beams is shown in the annexed diagram, which is a section view of the beams and cylinders, without the frame-work which supports the machine. The arrows show the direction of the cloth and of the cylinder, on the outer circumference of which are seen the ends of the frames in which the teazles are made fast. It will now be easily understood that, by the rapid revolution of the cylinder, and the slower motion of the cloth in a contrary direction, the loose fibres of the wool are brought to the surface. The longitudinal teazle-frames can be removed from the cylinder at pleasure, and when the teazles become clogged with wool, they are removed and cleaned with a comb by children.

---

[1] Cloth has recently been produced by the felting process alone, without the aid of weaving. Some machinery has been erected at Leeds, and it is expected to succeed. In France, cloth has been produced by the same invention. The scheme is not new, for as early as 1794, Mr Joseph Booth took out a patent for the production of cloth without weaving; but after being tried at Taunton, at Lewisham in Kent, and at Merton in Surrey, it was abandoned. We trust the present effort will be successful.

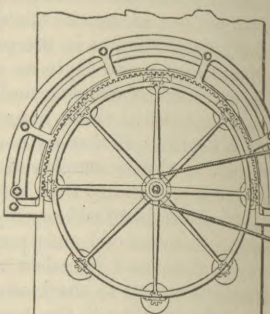
[2] "Here the Dutchmen found fuller's earth, a precious treasure, whereof England hath better than all Christendom beside; so that nature may seem to point out our land for the staple of drapery, if the idlenesse of her inhabitants be not the only hindrance thereof."—Fuller's Church History.



The most recent invention of a gig-mill with metallic teazles is that of Mr Atkinson; but we have never had the good fortune to see it in operation, nor do we know what success it has been attended with. It does not differ materially from the gig-mill just described. A series of longitudinal teazle-cards takes the place of the teazles; these teazle-cards rest on a spring, which gives them elasticity, and prevents any damage to the cloth. The teeth incline slightly in the direction of the line of motion, and they are cleaned by a wheel similar to the cleaner of a wool-card. Dr Ure states that the pile is more perfectly raised by this machine, and the nap of the cloth is much softer. The superiority of the teazle over wires arises from the tendency of the former to break off when they meet with any knot or inequality, which the metallic teazle-cards would tear out. The spring with which Mr Atkinson's gig-mill is fitted may perhaps correct this.

The mode of winding the cloth from one roller to another has also varied from time to time, still varies in different factories, and has even been the subject of a patent by Mr Walker of Mill-Shaw, in the township of Beeston, near Leeds. Mr Walker's improvement consists of five rollers instead of three. Two are immediately over the cylinder. The lower one brings the cloth close to it. The effect of this lower roller is to cause the cloth to be operated upon by a greater number of the rows of teazles, as the cloth touches the cylinder for about one fifth of its circumference. It then passes round another roller and ascends to a second pair, round one of which it is wound. The dotted lines in the above figure show this improvement.

When the fibre has thus been torn to the surface, the pile so raised is cropped or sheared. This, like all the other operations of cloth-making, was formerly performed by hand, a large pair of shears being employed for the purpose. But the disposition to apply machinery to every process of manufacture was not here neglected; and in the early part of this century a machine was invented, in which the shears were retained, but all their motions were regulated by machinery. The cloth was stretched horizontally on a frame by means of two cloth beams or rollers situated at each end at the lower part of the frame. Two pair of shears were then so fixed as to clip the surface of the cloth, being moved by two small cranks. Upon this first machine there have been many improvements; but it will be sufficient to describe the most recent, which has the merit of being extremely simple, and will probably supersede all others. It is the invention of Mr George Oldland of Hilsley in Gloucestershire, and was patented in 1832. It will be readily understood from the annexed figure, which represents the machine in operation against a piece of cloth. The machine consists of a fixed semicircular rack, within or rather behind which is a cutting edge, called by the inventor a *ledger-blade;* and a large revolving wheel, armed with eight small cutting discs, which, being in contact with the ledger-blade, form when in motion a series of far more delicate shears than have hitherto been applied to the process of cloth-shearing.



It will be observed that each cutting disc has a toothed pinion, working in the semicircular rack, which, as the larger wheel revolves, imparts to the cutting discs an independent rotary motion, in addition to their revolution with the large wheel. These motions have not inaptly been likened to those of a planet round its axis and its orbit. The other machine in use consists of an iron cylinder, around which is a spiral cutting blade, which is made to revolve with great rapidity, cutting the pile of the cloth immediately in contact beneath it, the cloth being stretched in a longitudinal moving frame.

Superfine cloths are cut and raised several times. In the west of England the first raising is called *roughing,* in which process the cloth is torn by the teazles both ways. After being sheared, it is subjected to the gig-mill in one direction only, which is called *mozing.* It is afterwards cut and teazled several times.

In most cases the cloth is subjected to an operation which imparts great lustre to it, and at the same time prevents its spotting when used. This operation is called roller-boiling, or patenting. The cloth is tightly wound round rollers, and is immersed in water heated to 180° of Fahrenheit for twenty-four hours, when it is once more stretched upon the tenters and dried. Mr William Hirst of Leeds, a great improver of the cloth-manufacture, finding the long exposure to heat injurious, proposed an alternate and intermitted immersion in hot and cold water, and his method is said to have been attended with great success.

The cloth is now removed to the brushing machine, a system of brushes affixed to cylinders. In its passage the cloth is exposed to steam, which escapes in minute jets from a copper box, extending the whole length of the machine. For the purpose of brushing, the cloth is made into an endless web by stitching the ends together, and the brushing is continued as long as may be deemed necessary.

Before the final brushing, mozing, or finishing, is given to it, however, it is subjected to a further examination before the light and on the surface, and is picked, fine-drawn, and marked. The picking is to remove all blemishes, similar to the process of burling, already described; the fine-drawing is to close any minute hole or break in the fabric; and the marking is the working in, with white or yellow silk, a word indicative of the quality and number of the piece, such as Saxony, extra superfine, and so forth.

The pile is again brushed, and after the final dressing is thus given to it, it is pressed in a hydraulic press. Between each fold of the cloth is placed a polished pressing board, similar to those used by printers for pressing the sheets of books. Between each piece of cloth, for many are pressed at the same time, are two iron-plates, each one half the width of the cloth. If the cloth is to be hot pressed, an operation not applied to the best cloths, as the patenting supersedes the necessity of this process, these plates are heated; but this only gives a gloss which is a poor substitute for that beautiful face which our finest cloths exhibit. The cloth is now finished, and is packed in bales for market. Sometimes it is cut into ends or half-pieces.

With respect to the worsted manufacture, we need not tax the reader's attention at any great length, as most of the processes have been described in other articles, to which we shall refer.

The wool employed in the worsted manufacture is the long or combing, as distinguished from the short or clothing wool; and the object of all the preparatory processes is to facilitate the production of a finer and more perfectly spun thread than would be fit for fulled cloth. By the operations of worsted spinning, indeed, the felting property of the wool is greatly impaired, though not wholly destroyed; and the worsted fabric is not homogeneous, like the fulled cloth, but is reticulated like linen and cotton fabrics.

The several processes of a worsted factory are as follows:

1. Sorting,
2. Washing,
3. Drying,
4. Plucking,
5. Combing,
6. Breaking,
7. Drawing,
8. Roving,
9. Spinning,
10. Reeling,
11. Weaving,

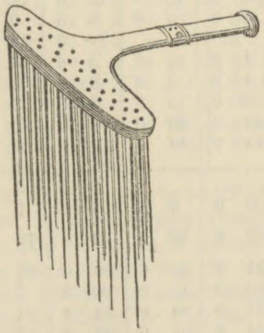
&c. &c.

For the worsted manufacture, the washing of the wool is very carefully performed with soap and water, the greater part of the moisture being pressed out between rollers. The wool is then carried to the drying room, where it is spread on the floor which is over the boilers of the steam-engine, by which a high temperature is kept up.

When the wool is thoroughly dried, it is passed through a machine called a plucker, which consists of a pair of spiked rollers fed by an endless apron. By the revolving spikes of the machine the fibres of the wool are cleansed and straightened; and as the interior is furnished with a fan or blower, the wool is blown out at the opposite end of the machine.

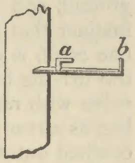
The wool is now ready for the process of combing, which is performed either by the hand or by machinery; but as none of the various combing machines which have been invented has attained that perfection which has been imparted to other automatic contrivances, the finest long wools are invariably combed by hand. This is to be deplored, as the operation is certainly not healthy. Great heat is required to keep the combs in a proper state, and this heat is produced by charcoal.

Each comber has two pair of combs, one pair having two rows of teeth, and the other three rows for the last combing. These teeth are fixed in a wooden stock furnished with a handle, as in the annexed figure. The rows of teeth are one third of an inch apart.



For heating the combs the workman has a peculiar kind of stove, furnished with a hot-plate at top, covered with another plate to confine the heat, there being just space between the two to admit the prongs of the combs. This stove is generally heated with charcoal, but in some factories steam has been applied to the heating of the combs, and we believe it has been attended with success.

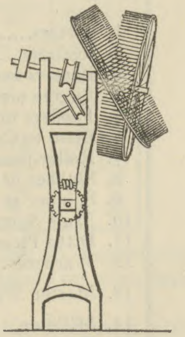
The workman has also a post affixed in the combing room, with an iron stem or receiver for the combs, with an upturned end which enters the hole in the middle of the handle of the comb, whilst at the other end of the stem is a pin which enters the hollow end of the handle. The operation of both these pins is to keep the comb sufficiently firm for the workman's purpose. In the annexed figure, *a* exhibits the pin which enters the end of the handle, and *b* the upturned end, to which the hole in the middle of the handle of the comb is adapted.



The combing operation is thus performed. The comber first takes a handful of wool of about four ounces, and sprinkles upon it a quantity of oil varying from one fortieth to one sixtieth of the weight of the wool. One of the combs, duly heated, is affixed to the post with the teeth upwards, and the comber, taking half the oiled wool in his hands, throws successive portions over the teeth of the comb, drawing it through and through, and leaving a portion of the wool on the comb till the whole is deposited. The comb is now placed with its points in the stove, and the wool hanging down so as to become heated. The other comb then takes the place of the first on the post, and receives the other half of the wool, when it is also removed to the stove. When the combs are sufficiently heated, the comber takes one in each hand. That in the left he holds over his knee, and with that in his right he combs the wool upon the first, passing the teeth of one comb into the wool upon the other, beginning with the extremities of the fibres, and continuing till he reaches the thicker mass of wool, near to the teeth of the comb. Thus the combs gradually approach each other, but without touching, as that would break the fibres instead of laying them parallel, which is the object of combing.

In order that the wool on both combs may be combed equally, the comber frequently changes hands; but when it is nearly sufficiently combed, he continues to comb off the one comb on to the other, so that nearly all the wool is gathered upon one comb, and hangs down in a long lock. This comb he warms for a short time, and fixes in the post, and proceeds to draw off the fleece in a continuous sliver. A small portion of short wool remains on the combs after the sliver has been drawn off. This is called *noils*, and is sold to the cloth-makers. The wool then undergoes a second combing at a lower temperature, and being collected in parcels of ten slivers, is ready for the next operation.

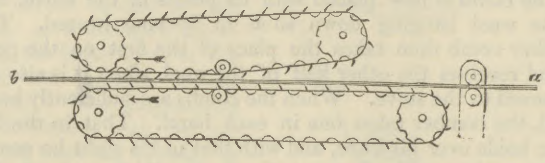
Several machines have been invented, designed to supersede the hand-combs. That which has been adopted to a considerable extent, and which we had an opportunity of seeing in full operation in the worsted spinning establishment of the late firm of Messrs Hindes and Derham at Leeds, is a foreign invention, but patented in this country by Mr John Platt of Salford, in November 1827, so that it has now stood the test of fourteen years' trial. It consists of two revolving combs, fixed in a frame, as in the annexed figure, and inclined at an angle of twenty-seven degrees. These wheels are in the ordinary form, with comb-teeth set at the edge of the rim, at right angles to the radii of the wheel. These wheels are made to revolve with great rapidity at first, at such a distance that the extremities of the wool, thrown off by centrifugal force, can alone be combed; but the circular combs are made gradually to approach each other, so as to imitate the hand process, as already described. This motion is effected by mounting the axle of one of the wheels in slides; the traverse movement being effected by means of an endless screw, attached to the under part of the frame. The frame-work of th



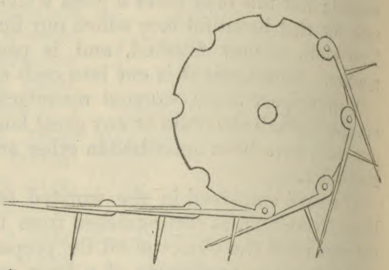
wheels is hollow, and steam circulates freely in it, so as to keep up the required degree of temperature.

The circular combs are fed by a boy, who sits on the ground, and throws the wool upon the teeth in the same manner that the comber does on the hand-comb. When one comb is charged, they are thrown into gear by shifting the driving belt on to the proper pulley; and as they revolve with rapidity against each other, gradually approaching, as already described, the whole length of the staple is combed out smooth. They are then thrown out of gear, and one end of the sliver being drawn through rollers, the sliver is pulled off by a boy. The *noils* being then removed, the machine is charged anew.

After the wool has been combed by one or other of the above means, it is removed to the breaking frame, which opens out any fibres which may have escaped from the combs in a partially felted state. The principal part of the breaking frame consists of two rows of endless comb-chains, of which one pair is exhibited in the annexed figure.



The reader must bear in mind that the frame-work is omitted in the drawing, as not being essential to the due understanding of the process. The wool is introduced between the feed-rollers at *a*, by means of an endless apron, upon which equal weights of wool are uniformly spread out from time to time. The teeth of the endless combs are arranged alternately, so that those of the upper are midway between those of the under comb-chain. The arrows indicate the direction of the motion, and both move with the same velocity. The two small rollers in the centre are merely to give the chain of combs a due degree of tension. After the wool has passed through the part of the machine here delineated, it is received by two rollers of the same diameter as the feed-rollers. The sliver then passes through a copper trumpet-shaped funnel, and then between another pair of rollers, and falls into a tin can. The respective velocities of the several parts of the machine are as follows. The velocity of the comb-chain is twice that of the feed-rollers, that of the second or receiving rollers (not shewn) twice that of the chain, and that of the last pair a little greater than the second, simply because their diameter is a little more.



The annexed enlarged view of one of the fluted cylinders, around which the endless chain revolves, will better explain the manner in which the comb-chain is formed, and the manner in which it operates. The chain is formed of a series of small rectangular pieces of tin, the half of one overlapping the other. The hinges are formed by little discs of the metal, which are turned up at right angles. The teeth are soldered to each piece of tin; and in the end which overlaps is cut a groove, to admit of the free motion of the teeth as the leaves pass over the cylinders. So long as the chain is clear of the cylinders, the tin leaves lie evenly, one upon the other; but as soon as the chain meets the cylinders, the overlapping ends are lifted, as shown in the diagram, and the wool upon the teeth is cleaned off or disengaged, so as to be ready to be taken up by the second pair of rollers, passed through the funnel between the last pair of rollers, and into the can, as already described.

The sliver is now ready for the drawing frame; but here our task is at an end. The operations of the drawing frame, the roving frame, and the spinning throstle, have been minutely described in the articles COTTON MANUFACTURE and SPINNING, and the article WEAVING will fill up what is there and here wanting.

A few words must yet be added on the condition of the people employed, and on the future prosperity of the manufacture. The following table is from Mr Miles's Report on the condition of the hand-loom weavers of the west of England.[1]

Statement of the Average Wages of different Classes of Work-people connected with the Manufacture of Woollen Cloth in the County of Gloucester, from the year 1808 *to* 1838, *shewing the Decrease per cent. in the Wages of each Class.*

Description of Work-people.	By whom the Labour is performed.	Amount of Wages paid in the Year.

---

[1] Assistant Commissioners' Reports, part v. p. 374.

In the Report of Mr Chapman for the west riding of Yorkshire, there is a detailed statement, from the weavers' own lips, of the earnings of thirty-three individuals, ranging from 7s. 6d. per week to 26s., varying according to age, strength, industry, and skill. These varying circumstances are stated, and certainly give a better view of the possible and actual earnings of men than any statement of averages. But although an average may be fallacious, it may be serviceable to ascertain at what points in the scale the largest number of cases occurs. We find it stated that

4 earned above 20s.
9 ... from 16s. to 20s.
1[illegible] ... ... 12s. to 16s.
4 earned from 10s. to 12s.
3 ... under 10s.

As the manufacture of the west riding has improved, the quantity of work has much increased without any increase of price, so that the weekly earnings are said greatly to have diminished within the last twenty years. Wages in Yorkshire are paid by the *string*, a measure of ten feet, being higher according to the *set*, as it is called, that is, the number of *porteths* or thirty-eight threads of warp in the width. Thus eighty is deemed a medium set, and has now 22,800 yards of weft in each string, or 5700 picks or shots; whereas in 1817 the same set had only 12,540 yards, or 3135 picks, the effect of this increased wefting. The necessary consequence of the improvement in the manufacture upon wages is shown in the following table.

Years.	Weight of Weft per String.	Number of Skeins per String.	Number of Yards of Weft per String.	Price paid for Weaving per String.	Average Weekly Earnings.
	Lbs. oz.			*s. d.*	*L. s.*
817 to 1822......	2 12	8	12,540	1 10	1 4
22 to 1827......	3 0	9½	14,440	2 0	1 0
27 to 1832......	3 4	12	18,240	2 0	0 15
32 to 1837......	3 8	15	22,800	2 1	0 9

The wages of the several operatives employed in October 1838 in the establishment of Messrs Hindes and Derham were as follows:

	L.	*s.*	*d.*		*L.*	*s.*	*d.*
Wool-sorters......	1	6	3½	to	1	10	0
Overlooker......					1	10	0
Combers, by hand......	0	14	9	to	1	6	6
Overlooker, 28s., with a house worth 5s......				=	1	13	0
By machine (boys)......	0	4	0	to	0	10	0
Overlooker......					1	4	0
Washers (paid by the week, not by the job)					0	18	0
Preparers (at the drawing frames), girls......	0	6	6	to	0	7	0
Spinners, girls under 13......	0	1	6	to	0	2	0
... over 13......	0	3	0	to	0	6	0
Overlookers in both departments......	0	18	0	to	1	1	0
Reelers, girls and women......	0	8	5	to	0	13	9
Bunchers, who make up the hanks into packets, girls and women......	0	7	6	to	0	8	0
Men (who are overlookers)......	0	18	0	to	1	4	0
Packers, men......					0	18	0
Engine-man......					1	4	0
Fireman......					0	16	0

But the most important feature in the condition of the weavers, as pointed out in Mr Chapman's Report, is, that in 1800, and for some few years after, money wages were as low, and perhaps lower, than in 1838; that about the year 1804 or 1806, wages advanced; that they continued high until 1815 or 1816, since which time they have declined, but not quite to the point they were at in 1800. The following statement confirms this view.

Weekly Earnings of a skilful Worsted Weaver, from 1787 *to* 1838.

1787......10s.	1815...31s. 6d.	1829...20s.	1835...15s. 6d.
1800......10s.	1820...21s.	1831...18s.	1836...15s. 6d.
1804......17s.	1822...24s.	1833...17s.	1837...14s.
1814......34s. 6d.	1824...21s.	1834...16s.	1838...12s. 6d.

The high wages which prevailed from 1804 to 1815 arose entirely out of the improvements in spinning. The quantity of yarn was so great that it was difficult to get weavers, and they were enabled to make their own terms; but the profits of weaving soon increased the supply of weavers. Children were extensively taught to weave; and as, in the case of cotton and worsted, the work is light, the labour of the parent was soon transferred to the child. In the case of woollen cloth, however, this could not take place. Cloth-weaving is emphatically a man's work; so that the cloth-weaver's wages are as much as those of the worsted and cotton-weaver put together, the average proportion being as 15s., 9s., and 6s. per week.

But a comparative statement of mere money wages does not inform us respecting the improving, stationary, or retrograde condition of the operative. For that purpose we must ascertain the command he has over the necessaries, comforts, and conveniencies of life. In this the following table will aid us.

Statement of the Prices of various Articles of Food and Household Stores for the use of Greenwich Hospital, from 1800 *to* 1835.

Year.	Flesh per Cwt.	Flour per Sack.	Butter per lb.	Cheese per lb.	Oatmeal per Bushel.	Salt per Bushel.	Beer per Barrel.	Candles per doz. lbs.	Price per Ration at Chelsea.
	L. s. d.	*L. s. d.*	*s. d.*	*d.*	*s. d.*	*s. d.*	*s. d.*	*s. d.*	*s. d.*
1800......	3 4 4	4 16 0	0 11⅛	6¼	14 0	...	...	...	0 8
1810......	3 12 6	4 8 4	1 1⅜	8⅛	11 7	...	...	...	0 11
1815......	3 8 0	2 4 9	1 2	8	10 3	19 9	15 4¾	11 7	1 0
1820......	3 10 4½	2 15 1	0 9½	7	13 4	19 9	15 10½	8 2¾	1 0
1825......	2 19 6½	2 13 4	0 10½	5¼	17 6	2 10	16 6¼	6 0	0 11¾
1830......	2 3 6	2 14 11	0 6½	6½	16 11	1 8	12 6½	5 3½	0 8¾
1835......	2 0 7½	1 11 0¾	0 7½	4	14 6	1 3	13 9½	5 2	0 7⅝

From this table it appears that every article in which the operative's wages are expended, is considerably cheaper now than at an earlier period; and if we could collect a similar comparative table of the price of clothing, the saving would be more conspicuous. In 1800 a week's wages would purchase ·71 of a bushel of wheat, or 17½ lbs. of flesh, or fifteen Chelsea rations; in 1837 a week's wages would purchase 1·64 bushels of wheat, or 34 lbs. of flesh, or twenty Chelsea rations, the ration consisting of one day's food for a man. On so much of the weaver's earnings as he expends in butter, cheese, salt, candles, &c. there is a saving of about 40 per cent., and on his clothing much more, so that 10s. in 1800 was certainly no more than 6s. 8d. at the present time.

The manufacturer's moral condition has improved with his physical condition. He is careful to educate his children to the full extent of his means; he evinces self-respect in all the relations of life, and therefore commands the respect of others. The legislature and the government have also of late years done much to elevate and improve his condition. The various provisions for the regulation of factories bring the employer under a system of necessary superintendence, proved to be necessary by the disclosure of much mismanagement and oppression. Objections may be urged against some of their details, but not to their principle. Children should be under the guardianship of the state; and however bad in principle it may be to interfere with the contract between the employer and employed, that rule must be broken through, or rather does not apply, where one of the parties is morally and legally unable to contract. It is certainly an evil of the factory system that the child is taken from his home, and converted into little better than a portion of the machine which he attends. Under improved regulations however this evil may be remedied, by withdrawing the younger children from the factory, and transferring them to their proper position, the school. This has been half done already; and if the state of opinion of the people themselves demanded such a step, the legislature might take it at once. But a government can never be much in advance of popular opinion, and it is generally behind it. Neither the employers nor the employed saw any thing disgraceful in working the tender infant instead of educating him; and no sound legislation can take place, no efficient public guardianship can be established, until the working people themselves believe that the employment of a child is disgraceful. When that belief becomes universal, as we are convinced it will, the factory age may as easily be limited to fourteen as to eight; but if it were now to be attempted, it would only be to throw the child upon the labour of the hand-loom, to the still further depression of the parents' already too scanty wages.

In all other respects, machinery has done much for the improvement of the operatives, and that in two ways. First, the better tool gives better wages; and, second, cheap production daily gives the working millions an increased command over the necessaries and comforts of life. It has been the fate of every machine to be opposed at its introduction; but as the working classes are almost always honest in their opposition, many of the machines which were most opposed are now most cherished. Nor ought this to excite surprise. The first view of a machine seems to threaten the displacement of labour, and it is only at a second and closer view that the labourer himself finds labour facilitated, production increased, and, in one way or another, fresh labour employed by more than the labour at first displaced; and as all improvements are adopted gradually, it generally happens that the increased employment anticipates the labour displaced. Can any one doubt that this has been the case with regard to the improvements in spinning? It is to these great improvements that we owe our pre-eminence in the cotton manufacture.

The woollen manufacture is certainly in a less organized state. The machinery employed is not so highly improved. The application of power is recent and imperfect; the jenny still performs much work that should be done by the self-acting mule; the whole work of preparing, including slubbing, is susceptible of great improvement. In every branch of the manufacture there is room for more economical arrangements. When the woollen manufacture has attained the perfection of machinery, and, above all, of organization, of which it is susceptible, the result must be a greatly increased trade. In the manufacture of woollens we cannot attain that extraordinary supremacy which we enjoy in the cotton manufacture, because cloth-making is to be found among the occupations of almost every people on the face of the earth. Still we see every prospect of an improved trade; and should increased freedom of commerce be concurrent with improved economy of manufactures, we believe that it is on the woollen and worsted manufacture of the west riding of Yorkshire that the increase would be most conspicuous. (D. L.)

WOOLER, a small town in the east division of Glendale, in the ward of Coquetdale and county of Northumberland. It stands on a gentle eminence, on the eastern declivity of the Cheviot Hills, at the foot of which runs the river Wooler, which falls into the Till about a mile below. It is a town of considerable antiquity; but all that now remains of its ancient state is a fragment or two of the castle walls. This vicinity is considered as healthy, and at one time was much frequented by invalids, many of whom were accustomed to drink goats' milk. The sole trade of Wooler depends on the articles required for the consumption of its inhabitants and those of the neighbourhood. Near to it are the remains of Roman and Scottish camps. It possesses a plain church, and several places of worship for Presbyterians. There is also a dispensary, with two subscription libraries. The market-day is on Thursday. The population in 1821 amounted to 1830, and in 1831 to 1926.

WOOLSTON, Thomas, was born at Northampton in 1669, and educated at Sidney College, Cambridge. He was chosen a fellow, and proceeded to the degree of B. D. His first appearance in the learned world was in 1705, in a work entitled "The old Apology for the Truth of the Christian Religion, against the Jews and Gentiles, revived." He afterwards wrote many pieces; but what made the most noise were his six Discourses on the Miracles of Christ, which occasioned a great number of books and pamphlets upon the subject, and raised a prosecution against him. At his trial in Guildhall, before the lord chief justice Raymond, he spoke several times himself; and urged, that "he thought it very hard that he should be tried by a set of men who, though otherwise very learned and worthy persons, were no more judges of the subjects on which he wrote, than himself was a judge of the most crabbed points of the law." He was sentenced to a year's imprisonment, and to pay a fine of L.100. He purchased the liberty of the rules of the king's bench, where he continued after the expiration of the year, being unable to pay the fine. The greatest obstruction to his deliverance from confinement was the obligation of giving security not to offend by any future writings, he being resolved to write again as freely as before. While some supposed him to have written with the settled intention of subverting Christianity under the pretence of defending it, others believed him disordered in his mind; and many circumstances concurred which gave countenance to this opinion. He died January 27, 1732–3, after an illness of four days; and, a few minutes before his death, uttered these words: "This is a struggle which all men must go through, and which I bear not only patiently, but with willingness." His body was interred in St George's church-yard, Southwark.

WOOLWICH, a large town and parish of the county of Kent, in the lathe of Sutton and the hundred of Blackheath, eight miles from London. It stands on the banks of the river Thames, and contains buildings of great extent connected with the public service, both naval and military. The dock-yard is well calculated for building and equipping ships of war of the largest size. It has attached to it an extensive rope-walk; the building called the Red House, for curing meat for the use of the navy; the government bake-house, a most extensive gun-yard, and magazines for securing in time of peace, and for arranging for immediate service, every thing requisite for fitting out a large fleet in a few days. The barrack for the artillery is a vast and magnificent pile of building, and near to a large field called the *Warren*, in which cannon and mortars are exercised, and experiments made in the practice of gunnery.

In an adjoining yard is the laboratory, where the several kinds of fire-working are carried on, and the most destructive projectiles are prepared. There is also the Royal Academy, with its appropriate professors and masters, in which the officers of the engineers and artillery receive their professional instructions. Woolwich has a good parish church; and the weekly market, on Friday, is well supplied. The population amounted in 1821 to 17,008, and in 1831 to 17,661.

WOOTTON-BASSET, a market-town in the county of Wilts and hundred of Kingsbridge, eighty-nine miles from London. It stands on a gentle eminence, which commands an extensive view, and consists of one long street. It is a poor place, with mean houses, and has an inconsiderable market on Friday. Until 1832, it returned two members to parliament. The population amounted in 1821 to 1701, and in 1831 to 1896.

WOOTTON-UNDER-EDGE, a town of the county of Gloucester, in the hundred of Berkeley, 108 miles from London. It is well built and pleasantly situated, and has a handsome church, in which are several monuments to members of the Berkeley family. It has a good market on Friday. Some of the finer cloths are made here. The population amounted in 1821 to 5004, and in 1831 to 5482.

WORCESTER, an inland English county in the Oxford circuit, and nearly in the centre of the kingdom. It is bounded on the north by Staffordshire and Shropshire, on the south by Gloucestershire, and on the east by Warwickshire. Its figure is very irregular; and it is remarkable for having several detached portions scattered about the neighbouring counties, which makes it difficult to be accurate in its dimensions. It may be stated as about thirty miles in length and twenty-four in breadth, and to be 723 square miles or 462,720 acres in extent.

The population of the county at the four decennial enumerations has been as follows: in 1801, 139,331; in 1811, 160,546; in 1821, 184,424; and in 1831, 211,400. At the last of these periods the males were 103,383 and the females 107,982. The number of dwelling-houses was 41,406, inhabited by 45,512 families; of whom 14,654 were chiefly employed in agriculture; 19,040 were chiefly employed in trade, manufactures, and handicraft; and 11,828 were not comprised in either of the preceding classes. At the same period the number of males twenty years of age was 52,796; the occupiers of land employing labourers were 2636; the occupiers not employing labourers, 1260; the labourers employed in agriculture, 14,590; the labourers employed in manufactures, and in making manufacturing machinery, were 8024; those employed in retail trade or handicraft, as masters or workmen, 12,693; those described as bankers, professional and other educated men, 2085; labourers employed in labour not agricultural, 6544; other males under twenty years, except servants, 2885; male servants twenty years of age, 1079; male servants under twenty years of age, 446; female servants, 8162.

There is a soft beauty on the face of this county, when viewed from any elevation, such as the Malvern or Abberley Hills, which is highly gratifying. From such spots the state of its cultivation appears to great advantage, as there are no parts of any considerable extent so barren or neglected as to be destitute of an agreeable and profitable verdure. With the exception of those hills, the former of which rise to the height of 1440 feet, the whole county consists of gentle undulations, wholly enclosed, well wooded, and intersected by the great rivers Severn and Avon, and their several tributary streams. The abundance of orchards of pear-trees, and the scattered hop plantations, give a peculiar richness to the autumnal scenery. Even the poorer parts of the county, between the towns of Droitwich and Bromsgrove, have of late been cultivated; and though they do not rival in beauty the vale of Evesham, they are far from the aspect of sterility which they exhibited twenty years ago. The farms are generally of small extent, from forty to three hundred acres, and the cultivation is generally well conducted. The arable land, which, in the rotation of crops, produces artificial grasses, is estimated to be 360,000 acres; the permanent grass land 100,000 acres; and the woods, wastes, rivers, roads, sites of towns, and gardens, 40,000. The crops of wheat, barley, and especially of beans, are more productive than the average of England. Hops are extensively cultivated, and the pear-trees are so abundant and so productive as to afford perry for the common drink of the labourers in agriculture. There is no breed of cattle peculiar to Worcestershire, as it is found more profitable to buy oxen and sheep in a lean condition from poorer districts, and to fatten them in this county, than to breed them on its rich soil.

Worcester.

The great rivers Severn and Avon are both navigable, the former to an extent of nearly two hundred miles from its mouth, and the latter to Stratford from its junction with the former. The Severn abounds with salmon, shad, and lampreys, though those delicious fish are never known to ascend the Avon. The other rivers are, the Stour, the Salwarpe, the Ledden, and the Rea. This county has partaken largely of the benefit communicated by internal navigation. The canals are, the Trent and Severn, the Droitwich, the Worcester and Birmingham, the Dudley and Leominster. The town of Stourport has risen into importance since the extension of canals, and exhibits a large maritime town in the centre of the kingdom, connecting its various productions in a focus, and distributing them where needed.

Although this county has hitherto had no railways formed through it, yet as one portion of it is in contact with the town of Birmingham, that part has, by the vicinity, the means of the most rapid communication with London, Liverpool, and Manchester; and projects are now on foot which in a few years may give facilities of speedy intercourse with Bristol and Exeter, and may perhaps be extended to Plymouth.

The county possesses a variety of manufactures in hardware, carpet-making, gloves, and china. At Dudley, Stourbridge, and Old Swinford, about 450 males upwards of twenty years of age are employed at the forges, who make anvils, chains, and the heavier kinds of iron tools and machinery. At Woolverley, and some other neighbouring villages, about 280 men make gun-barrels, edge-tools, and files. At Tardebig, and the parishes near it, 540 men make needles and fish-hooks. The number of nailers throughout the county is about 3000, chiefly in and near Bromsgrove, Dudley, and Swinford. At and around Kidderminster, 2300 men are employed in making carpets, and in preparing materials for that manufacture. At Worcester, and in its suburbs, nearly 1000 men, and a much greater number of females, are employed in making gloves; and about fifty men, besides many females, are occupied in making china, chiefly in burnishing and other delicate operations. At Pershore, some men are employed in making watch-springs.

The salt made at Droitwich supplies nearly one half of England with that indispensable article. The duty collected there before the abatement of the tax amounted to more than L.1000 per day. The water, from which the salt is made by evaporation, is more highly saturated than any other that has been discovered. Researches in the bowels of the earth have shown that a river of salt water, about twenty-two inches in depth, runs about 250 feet below the surface. Immediately above this subterranean stream is a bed of gypsum 130 feet thick. When this stratum is penetrated by the borer, the spring rises to the surface, and yields a never-failing supply of water, so fully saturated that no more salt can be dissolved in it. The springs at Droitwich hold in solution about one fourth of their weight in salt; and no other in England holds more than a ninth. The subterraneous river runs over a bed of rock-salt, whose thickness has not yet been ascertained. Besides the springs at Droitwich, other mineral springs are found at Malvern, which are resorted to for their healing properties, as well as for the pure air of the district. The combinations of the wells are carbonate of soda, carbonate of lime, carbonate of magnesia, carbonate of iron, sulphate of soda, and muriate of soda.

The most considerable places, and their population in the year 1831, were the following.

Worcester	18,610	Tardebig	3627
Dudley	23,043	Malvern, Great and Little	3535
Kidderminster	20,865	Droitwich	2487
Bromsgrove	8,612	Upton on Severn	2343
Stourbridge	6,148	Pershore	2080
Evesham	3,991		
Bewdley	3,908		

The titles derived from the county are the marquisate of Worcester and the earldom of Beauchamp. For election purposes the county has been formed into two divisions, distinguished as the eastern and the western, each of which elects two members to the House of Commons. The election for the eastern division is held at Droitwich; and the other polling places are Pershore, Shipston, and Stourbridge. The election for the western is held at Worcester; and the other polling places are Upton, Stourport, and Tenbury. The city of Worcester and the borough of Evesham, as formerly, return two members, and Bewdley one. By the reform bill, Droitwich has been deprived of one of its members, and Kidderminster and Dudley have been constituted boroughs, each electing one member.

Among the numerous seats of noblemen and gentlemen in this county, the most distinguished are, Madresfield, Lord Beauchamp; Hagley, Lord Lyttelton; Croome Court, earl of Coventry; Northwick, Lord Northwick; Hartlebury Castle, bishop of Worcester; Dailsford, late Warren Hastings; Ombersley Court, marquis of Downshire; Hewell Grange, earl of Plymouth; Hanbury Hall, John Phillips; Overbury, James Martin; Winterdyne House, William Moselay; Westwood House, Sir Herbert Packington; and Whitely Court, Lord Foley.[1]

WORCESTER city, the capital of the county of that name, in nearly the centre of England. It is finely situated on a gradual ascent from the left bank of the river Severn, over which is an elegant stone bridge. The river is navigable for barges far above the town; and after the winter rains, timber is floated down from Montgomeryshire in Wales. The trade by the river is very considerable, as by that channel the foreign and colonial productions required by the inhabitants are supplied from Liverpool or from Bristol. One branch of trade, that of culinary salt from the brine springs of Droitwich, about six miles higher up the river, and connected with it by a short canal, is very extensive, as it supplies some of the western counties of England, and some parts of South Wales, with that indispensable article.

In past time this city had some trade in making woollen cloths and carpets; but that business has departed, and now the chief manufacturing employment is the making of leather gloves. There is also a manufactory of porcelain, more remarkable for the beauty of the work than for its being in any extensive demand. The city was anciently surrounded with walls, in which were six gates, some traces of which are still to be seen. Worcester suffered much during the wars between the rival houses of York and Lancaster; but the most remarkable event of a historical nature was the great battle fought here in 1650, by the English army under Cromwell, and the Scottish army under the command of King Charles II. The loss of the king's troops is stated to have been 2000 men killed and 8000 taken prisoners. Most of the latter were sold as slaves to the colonies in America and the West Indies. The destruction of the walls and gates was ordered by Cromwell after his decisive victory. It is, generally speaking, a well-built city, and the chief street, the Foregate, is remarkably fine. The guildhall, in that street, is a handsome structure, finished in 1723. Its front, which is of brick, is ornamented with stone quoins, with mouldings and tablets to the windows, of the same materials. The principal entrance, after ascending some semicircular steps, is ornamented with columns of the composite order, highly enriched, and crowned with an indented cornice and open pediment, in which are the city arms. On each side of this principal entrance are the statues of the two kings Charles, in niches; and over it a statue of Queen Anne. The county-jail and the county-hall are fine buildings. The market-house is another fine edifice. It is highly ornamented, and conveniently arranged for the purpose it is intended to serve. The cathedral, whose effect is lessened by the close approach of some of the surrounding dwellings, is a noble specimen of Gothic simplicity. It was first erected by Ethelred, king of Mercia, in 680, when it was a convent of secular priests. Soon after the Norman conquest, it was laid in ashes by the Welsh, and was afterwards rebuilt with greater magnificence, though not entirely completed until the year 1374. The building is 394 feet in length, 78 in breadth, and the tower is 162 feet high. On the south side is a chapel of curious workmanship. Both the church and the cloisters are arched with stone of a reddish colour; and in the tower are eight good bells, the largest of which weighs 6600 pounds. The elegant window in the west front was constructed on occasion of the visit of George III. to this city in 1788, when, at the music meeting, the throne was placed near to it. Another window was built at the east end in 1792, containing some excellent painting in glass. The pulpit is octagonal, and of stone, curiously carved in the Gothic manner, with the symbols of the four evangelists, and a representation of the New Jerusalem, as described in the book of Revelation. The altar-piece is of plain oak, having in the centre a painting of the descent from the cross. The chief monument is that of King John, standing in the midst of the choir; but the body was interred under a small stone in the eastern part of the church. On each side of the figure of the king are those of the bishops Wolstan and Oswald. On the south side of the altar is Prince Arthur's sepulchral chapel, a most curious piece of antique workmanship, which was repaired and beautified in 1791. It consists of five orders of images, viz. virgins, bishops, kings, confessors, and angels, ornamented with the various badges of royalty; and under an arched roof is the tomb, of fine marble. There are also several other handsome monuments, one of Bishop Hough, by Roubiliac. The cloisters, where the monks formerly resided, and which are now inhabited by the dignitaries of the cathedral, are 125 feet by 120, and sixteen feet in breadth. The vaulted roof is adorned with a variety of sculptures. The bishop's palace stands near the cathedral, in a most commanding situation, overlooking the river Severn, which flows at the bottom of the garden.

There are nine parish churches within and two without the walls. The most remarkable of them are, St Michael's, a very ancient specimen of ecclesiastical architecture; St Andrew's, with a lofty and well-proportioned tower, built in the eleventh century; All-Saints, which was rebuilt in 1742, an edifice of the modern style; St Martin's, a handsome edifice, finished in 1772, after four years' labour; and St Nicholas, of which the interior is neat and commodious. Its style of architecture, executed in stone, is very pleasing, the front being of the Doric order, with six pilasters, the lower part rusticated, and the roof balustraded. The other churches do not deserve particular notice. Besides these, there are places of worship for the Roman Catholics, the Quakers, and several other denominations of protestant dissenters.

---

[1] See Nashe's Survey of Worcestershire; Pitt's Agricultural Survey; Brewer's Worcestershire.

The country around Worcester is highly fertile, and the supply of every kind of provisions is abundant in the markets, which are held every Wednesday, Friday, and Saturday. The river Severn affords an abundant supply of salmon and lampreys, and other fresh-water fish. Among other articles of cultivation, hops are the most extensive; and this city is the largest depôt for that article after Maidstone and Canterbury. Coals are supplied by the Severn at a cheap rate; and, under all circumstances, few places are better adapted for the residence of families who wish to unite economy with comfort.

The city gives the title of marquis to the eldest son of the duke of Beaufort. It returns two members to the House of Commons; and by the late law it is divided into six wards, and is governed by a mayor, twelve aldermen, and thirty-five councillors, with justices of the peace appointed by the crown. The population amounted in 1821 to 17,849, and in 1831 to 18,610. Worcester is 111 miles from London, fifty-five from Oxford, and twenty-two from Birmingham, with excellent roads in every direction around it.

WORCESTER, Edward Somerset, Marquis of, was a distinguished political character in the time of Charles I., by whom he was created earl of Glamorgan, while heir apparent to the marquis of Worcester. This nobleman flourished chiefly in the reign of Charles I., and seems to have been a most zealous adherent to the cause of that unfortunate monarch, on whose account it is said that he and his father wasted an immense sum. Of this the king was so sensible, that he granted to the earl a most extraordinary patent, the chief powers of which were, to make him generalissimo of three armies, and admiral with nomination of his officers; to enable him to raise money by selling his majesty's woods, wardships, customs, and prerogatives; and to create by blank patents, to be filled up at Glamorgan's pleasure, from the rank of marquis to that of baronet. If any thing, says Lord Orford, could justify the delegation of such authority, besides his majesty having lost all authority when he conferred it, it was the promise with which the king concluded, of bestowing the princess Elizabeth on Glamorgan's son. This patent was given up by the marquis to the House of Peers after the restoration. He died in 1667, after he had published his celebrated work entitled "A Century of the Names and Scantlings of such Inventions as at present I can call to mind to have tried and perfected, which (my former notes being lost) I have, at the instance of a powerful friend, endeavoured now, in the year 1655, to set these down in such a way as may sufficiently instruct me to put any of them in practice." Some of the inventions referred to in this work are the following. A ship-destroying engine, a coach-stopping engine, a balance water-work, a bucket fountain, an ebbing and flowing castle-clock, a tinder-box pistol, a pocket ladder, a most admirable way to raise weights, a stupendous water-work. For the last contrivance the marquis procured an act of parliament in 1663, for the sole benefit arising from it, one tenth of it being appropriated to Charles II. and his successors.

Various and very opposite opinions have been held with regard to the title of this nobleman to be considered as a mechanical genius. Lord Orford has pronounced his work an amazing piece of folly; and Mr Hume, speaking of his political conduct, says, "that the king judged aright of this nobleman's character, appears from his Century of Arts, or Scantling of Inventions, which is a ridiculous compound of lies, chimeras, and impossibilities, and shows what might be expected from such a man." It may be fairly presumed, that neither Lord Orford nor Mr Hume was qualified to judge of the marquis's work, otherwise a more temperate or more modified opinion would have been given. By others, its author has been regarded as one of the greatest mechanical geniuses; and he is considered as the inventor of the steam-engine, which he denominates a stupendous water-work. See Steam-Engine.

WORGAUM, a town of Hindustan, in the province of Aurungabad, situated twenty miles west of Poonah.

WORK, in the manege. To work a horse, is to exercise him at pace, trot, or gallop, and ride him at the manege. To work a horse upon volts, or head and haunches in or between two heels, is to passage him, or make him go sideways upon parallel lines.

To Work, in sea-language, is to direct the movements of a ship, by adapting the sails to the force and direction of the wind.

WORK-HOUSE, a place where indigent, vagrant, and idle people are set to work, and supplied with food and clothing. Work-houses are of two kinds, or at least are employed for two different purposes. Some are used as prisons for vagrants or sturdy beggars, who are there confined and compelled to labour for the benefit of the society which maintains them; whilst others, sometimes called *poor-houses*, are charitable asylums for such indigent persons as through age or infirmity are unable to support themselves by their own labour. See Poor-Laws.

WORKINGTON, a market-town of the county of Cumberland, in the ward of Allerdale, 311 miles from London. It stands on the sea-shore, where the rivers Derwent and Cocker enter the ocean. The coal-mines near it are the chief source of the trade, as they supply annual loading to hundreds of ships. There are also a considerable salmon fishery, and some works for refining salt. The population of the town amounted in 1821 to 6439, and in 1831 to 6415; but the parish contains other four townships, and the collective number of inhabitants at the census of 1831 was 7196.

WORKSOP, a market-town in the county of Nottingham and hundred of Bassetlaw, 143 miles from London. It stands in a pleasant valley near the source of the river Ryton. Here was formerly an Augustinian monastery, the chapel of which, in the cathedral form, is used as the parish church. Adjoining to the town there was formerly a magnificent seat belonging to the duke of Norfolk. There is a market on Wednesday. The population amounted in 1821 to 4567, and in 1831 to 5566.

WORM, Olaf, or *Olaus Wormius*, a learned Danish physician, was born on the 13th of May 1588, at Arhusen in Jutland. After beginning his studies at home, he resided in several foreign universities, and travelled to various parts of Europe for improvement. After having taken the degree of M. D. at Basel, he returned to his native country in 1613, and was made professor of polite literature in the university of Copenhagen. In 1615, he was translated to the chair of the Greek professor; and in 1624 to the professorship of physic, which he held till his death. These occupations did not hinder him from practising in his profession, and from being the fashionable physician: the king and court of Denmark always employed him; and Christian IV., as a recompense for his services, conferred on him a canonry of Lund. He published some pieces on subjects relating to his profession; several works in defence of Aristotle's philosophy; and several concerning the antiquities of Denmark and Norway; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died on the 7th of September 1654.

Worm, in *Gunnery*, a screw of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carabine, or pistol, being the same with the wad hook, only the one is more proper for small arms, and the other for cannon.

WORM, in *Chemistry*, is a long winding pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

WORMS, an ancient city of Germany, now in the principality of Hesse-Darmstadt and province of the Rhine, and the capital of the bailiwick of its own name. It stands on the Rhine, where the Eisbach falls into that river. It is surrounded with ancient and untenable fortifications, and is much reduced from the condition it once exhibited when it was an imperial city. It contains two Catholic, two Lutheran, and one reformed church, 910 houses, and 8100 inhabitants. It has some trade by the river and at its fairs, but chiefly in the products of the district. It is more remarkable for its antiquities and the historical recollections which it recalls. It was the seat of frequent diets of the empire. Long. 8. 15. 7. E. Lat. 49. 37. 49. N.

WORONESH, one of the governments or stadtholderates into which the Russian empire in Europe is divided. It takes the name from its capital city, and extends in north latitude from 48° 37′ to 52° 53′, and in east longitude from 38° 35′ to 14° 17′. It is bounded on the north by Tambow, on the north-east by Saratow, on the east and south-east by the country of the Don Cossacks, on the south-west by Jekaterinoslaw, and on the west by Slobodsk-Ukraine and Kursk. It comprehends the vast space, including the circle of Nowochopersk recently added to it, of 34,034 square miles, in which are sixteen cities and towns, 769 parishes with each its church, and numerous villages and hamlets. The inhabitants are 1,445,900, mostly of the race of the indigenous Russians, but having many Cossacks and some Gipsys mingled with them. There are also several newly-planted people, called colonists, of various races. With the exception of some Germans who have settled there, and keep separate, they all adhere to the Greek church. The nobles are less numerous than in some of the other governments, but more than one third of the whole inhabitants are their slaves.

The climate is temperate, as may be presumed from the latitude. The rivers seldom freeze till the end of December, and are open again in March. It is a healthy district, the people attain a great age, the cattle are large and strong, and the vegetable productions of the milder climates make their appearance in the southern parts. The grain chiefly cultivated is rye, some little wheat, barley, oats, buck-wheat, and, in the south, maize. Though the soil is fertile, from careless husbandry the product of corn rarely exceeds the consumption; but, on the other hand, the crops of flax and hemp supply considerable materials for commerce. Some wood for fuel likewise occasions a little trade by the rivers. The principal manufacture is coarse cloth from the wool of the province, which is chiefly used for the clothing of the troops. Some linen is also made; and there are several tanneries, distilleries, and breweries.

The city of Woronesh is the capital of the province, as well as of the circle of its name. It stands on a rising ground near that part of the river Don into which the river Woronesh falls. It is without fortifications, contains the palace of the governor and of the bishop, eighteen churches all built of stone, an ecclesiastical seminary, two monasteries, 3000 houses, and 20,300 inhabitants, who carry on some trade with Siberia and Orenburg. Here Peter the Great founded a dock-yard for building vessels, but it has since been removed to Towrow. It is 790 miles from St Petersburg. Long. 40. 48. 30. E. Lat. 51. 40. 30. N.

WORSHIP OF GOD (*cultus Dei*) amounts to the same with what we otherwise call *religion*. See RELIGION and THEOLOGY.

WORSTEAD, an ancient market-town in the county of Norfolk and hundred of Tunstead, only remarkable from having given its name to a kind of woollen thread. It has a small market on Saturday. The population amounted in 1821 to 706, and in 1831 to 830.

WORT, the infusion of malt, of which beer is made. See BREWING.

WORTHING, a town of the county of Sussex, fifty-nine miles from London, in the hundred of Brightford and rape of Bramber. It is in the parish of Broadwater, on the sea-shore, and within the last thirty years has been frequented for the purpose of sea-bathing. From a hamlet with a few fishing cottages, it has thus increased to an elegant and well-built town, containing churches and chapels, a market-house, and splendid hotels. The climate is mild, being defended from the north and east winds by the South-Down Hills. The population amounted in 1821 to 3725, and in 1831 to 4576.

WOTTON, SIR HENRY, an eminent writer, was the son of Thomas Wotton, Esq., and was born on the 30th of March 1568. He studied for some time at New College, Oxford, whence he removed to Queen's College, where he made a great progress in logic and philosophy; and wrote a tragedy for the use of that college, called *Tancredo*. According to Walton, he proceeded A. M. After leaving the university, he travelled into France, Germany, and Italy; and having spent about nine years abroad, he returned to England, and became secretary to Robert earl of Essex, with whom he continued till that earl was apprehended for high treason. He then retired to Florence, where he became known to the grand duke of Tuscany, who sent him privately with letters to James VI. king of Scotland, under the name of *Octavio Baldi*, to inform that king of a design against his life. Some months after he went back to Florence; but King James coming to the possession of the crown of England, Wotton returned home, was knighted by his majesty, and sent ambassador to the republic of Venice, and afterwards was employed in many other embassies to that and other courts; but the only reward he obtained for these services was his having the provostship of Eton College conferred upon him in the year 1623. He was ordained deacon, as the office could not be regularly held by a layman. He died in December 1639. After his decease, some of his manuscripts and printed tracts were published together in a volume, entitled *Reliquiæ Wottonianæ;* but he was the author of various works which are not included in this collection. His life by Isaac Walton is well known to the learned.

WOTTON, *William*, a learned divine and writer, was the son of Henry Wotton, B. D., rector of Wrentham in Suffolk, where he was born on the 13th of August 1666. He was educated by his father, a gentleman well skilled in the learned languages, under whom he made such amazing proficiency, that at five years of age it is said he could render several chapters of the gospels out of Latin and Greek, and many psalms in Hebrew, into his mother tongue. When he was very young he remembered the whole of almost every discourse he had heard, and often surprised a preacher by repeating his sermon to him. He was admitted into Catharine Hall in Cambridge some months before he was ten years old; when the progress he made in learning in that university engaged Dr Duport, then master of Magdalen College, and dean of Peterborough, to write an elegant copy of Latin verses in his praise. In 1679 he took the degree of A. B. when he was but twelve years and five months old; and the winter following he was invited to London by Dr Burnet, then preacher at the Rolls, who introduced him to most of the learned men in that city, and particularly to Dr Lloyd, bishop of St Asaph, to whom he recommended himself by repeating to him one of his sermons, as Dr Burnet had engaged he should. In 1691 he commenced B. D. The same year Bishop Lloyd gave him the sinecure of Llandrillo, in Denbighshire. He was afterwards made chaplain to the earl of Nottingham, then secretary of state, who presented him to the rectory of Middleton Keynes, in Bucks, and to whom he dedicated his "Reflections upon Ancient and Modern Learning." Lond. 1694. 8vo. In 1705, Bishop Burnet gave him a prebend in the church of Salisbury; and in 1707, Archbishop Tenison conferred upon him the degree of D. D. In 1714, the difficulties under which he laboured with respect to his private fortune obliged him to retire into South Wales, where he was treated with great kindness and humanity by the gentlemen of that country. He then wrote the "Memoirs of the Cathedral Churches of St David's and Llandaff," and his "Miscellaneous Discourses relating to the Traditions and Usages of the Scribes and Pharisees;" which were afterwards printed. He died on the 13th of February 1726. Dr Wotton was remarkable for his humanity and friendliness of temper; the narrowness of a party spirit never broke in upon any of his friendships; and his time and abilities were at the service of any person who was making advances in real learning. He wrote, besides the above works, 1. A History of Rome; 2. A Defence of his Reflections upon Ancient and Modern Learning; 3. A Discourse concerning the Languages of Babel; 4. Advice to a Young Student, with a Method of Study for the first four Years; and other learned pieces.

WOUNDS, in *Surgery*. See SURGERY.

WOW, a fortified town of Hindustan, province of Gujerat, district of Neyer, of which it may be considered as the capital. It is the residence of 1000 Rajpoot families. Long. 71. 23. E. Lat. 24. 11. N.

WOWAMIA, a town of Hindustan, province of Gujerat, on the eastern shore of the Runn, where there is a ferry for conveying travellers to the district of Cutch. Long. 70. [illegible]7. E. Lat. 22. 50. N.

WREATH, in *Heraldry*, a roll of fine linen or silk (like that of a Turkish turban), consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest.

WREN, SIR CHRISTOPHER, one of the most learned, scientific, and eminent architects of his age, was the son of Dr Christopher Wren, dean of Windsor, and was born on the 20th of October 1632. He studied at Wadham College, Oxford; where he took the degree of A. M. in 1653, and was chosen fellow of All Souls College. When very young he discovered a surprising genius for the mathematics; in which science he made great advances before he was sixteen years old. In 1657, he was made professor of astronomy at Gresham College, London; but he resigned this office in 1660, on his being chosen to the Savilian professorship of astronomy in Oxford. He was next year created LL. D., and in 1663 was elected fellow of the Royal Society. He was one of the commissioners for the reparation of St Paul's; and in 1665 travelled into France to examine the most beautiful edifices there, when he made many curious observations. At his return to England, he drew a noble plan for rebuilding the city of London after the fire. This plan he presented to parliament; and upon the decease of Sir John Denham in 1668, was made surveyor-general of his majesty's works. From that time he had the direction of a great number of public edifices, by which he acquired the highest reputation. He built the magnificent theatre at Oxford, St Paul's Cathedral, the churches of St Stephen Walbrook and St Mary-le-Bow; the Monument, the modern part of the palace of Hampton Court, Chelsea College, one of the wings of Greenwich Hospital, and many other beautiful edifices. He was president of the Royal Society, one of the commissioners of Chelsea College, and twice member of parliament, first for Plymouth in Devonshire, and then for Melcombe Regis in the same county. In 1718 he was removed from his place of surveyor-general. He died on the 21st of February 1723, in the ninety-first year of his age, and was interred in the vault under St Paul's. This eminent man also distinguished himself by many curious inventions and discoveries in natural philosophy; and, among many others, contrived an instrument for measuring the quantity of rain that falls on any space of land for a year. He devised various methods of rendering astronomical observations more accurate and easy; and was the first author of the anatomical experiment of injecting liquors into the veins of animals, &c. He translated into Latin Mr Oughtred's *Horologiographia Geometrica;* and wrote a Survey of the Cathedral Church of Salisbury, and other pieces. After his death his posthumous Works and draughts were published by his son.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground. Wrestling is an exercise of very great antiquity and fame. It was in use in the heroic age; witness Hercules, who wrestled with Antæus. It continued a long time in the highest repute, and had considerable rewards and honours assigned to it at the Olympic games. It was the custom for the athletæ to anoint their bodies with oil, to give the less hold to their antagonists.

WREXHAM, a market-town of the county of Denbigh, in North Wales, in the hundred of the same name, 188 miles from London and ten from Chester. It is finely situated on a rising ground, and has a church, in elegance and beauty surpassing many of the cathedrals of the kingdom, and richly adorned with images and curious carved work, and many handsome monuments. It has a neat town-hall, and a well-endowed free-school. What little trade there is consists in making flannels, but in the vicinity are considerable iron-works. It is a borough, and, conjointly with Denbigh, Holt, and Ruthin, returns one member to the House of Commons. There are markets on Monday and Thursday. The town consists of two parts, called Wrexham Abbot and Wrexham Regis, whose population amounted in 1821 to 4795, and in 1831 to 5484.

WRINGTON, a market-town of the county of Somerset, in the hundred of Brent and Wrington, 125 miles from London. It is chiefly noted as the birth-place of that great philosopher John Locke. It has a small market on Tuesday. The population amounted in 1821 to 1349, and in 1831 to 1540.

WRIT, in *Law*, signifies, in general, the king's precept in writing under seal, issuing out of some court, directed to the sheriff or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done. And, according to Fitzherbert, a writ is said to be a formal letter of the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the suit of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

WRITS, in civil actions, are either original or judicial. Original are such as are issued out of the court of chancery for the summoning of a defendant to appear, and are granted before the suit is commenced, in order to begin the same; and judicial writs issue out of the court where the original is returned, after the suit is begun.

WRITING, the art or act of signifying and conveying our ideas to others, by letters or characters visible to the eye.

The most ancient remains of writing which have been transmitted to us are upon hard substances, such as stones and metals, which were used by the ancients for edicts and matters of public notoriety. The decalogue was written on two tables of stone; but this practice was not peculiar to the Jews, for it was used by most of the eastern nations, as well as by the Greeks and Romans; and therefore the ridicule which Voltaire attempts to cast upon that part of the book of Genesis, where the people are commanded to write the law on stones, is absurd; for what is there said by no means implies that other materials might not be used on common occasions. The laws penal, civil, and ceremonial, among the Greeks, were engraven on tables of brass, which were called *cyrbes*.

We find that wood was also used for writing on in different countries. The Chinese, before the invention of paper, wrote or engraved with an iron tool upon thin boards or on bamboo. Pliny says that table-books of wood were in use before the time of Homer. These table-books were called by the Romans *pugillares*. The wood was cut into thin slices, and finely plained and polished. The writing was at first upon the bare wood, with an iron instrument called a *style*. In latter times these tables were usually waxed over, and written upon with that instrument. The matter written upon the tables which were thus waxed over was easily effaced, and by smoothing the wax new matter might be substituted in the place of what had been written before. The Greeks and Romans continued the use of waxed table-books long after the use of papyrus, leaves, and skins became common, because they were so convenient for correcting extemporary compositions.

Table-books of ivory are still used for memorandums, but they are commonly written upon with black-lead pencils. The practice of writing on table-books covered with wax was not entirely laid aside till the commencement of the fourteenth century.

The bark of trees was also used for writing by the ancients, and is so still in several parts of Asia. The same thing may be said of the leaves of trees. It is needless to observe the use of parchment and vellum, papyrus and paper, for writing; it is too well known. The method of fabricating these substances has been already described as they occurred in the order of the alphabet.

It is obvious, that when men wrote, or rather engraved, on hard substances, instruments of metal were necessary, such as the chisel and the stylus; but the latter was chiefly used for writing upon boards, waxed tablets, or on bark.

When the ancients wrote on softer materials than wood or metal, other instruments were used for writing with, of which reeds and canes seem to have been the first. Reeds and canes are still used as instruments for writing with by the Tartars, the Indians, the Persians, the Turks, and the Greeks. Pencils made of hair are used by the Chinese for their writing: they first liquefy their ink, and dip their pencils into it. Hair-pencils have likewise been used for writing in Europe. Large capital letters were made with them from the time of the Roman emperors till the sixteenth century. After the invention of printing they were drawn by the illuminators. Quills of geese, swans, peacocks, crows, and other birds, have been used in these western parts for writing with, but how long is not easy to ascertain. Isidorus Hispalensis, or Isidore of Seville, who lived about the middle of the seventh century, describes a pen made of a quill as used in his time. See BIBLIOGRAPHY, HIEROGLYPHICS, and LANGUAGES.

WUDWAN, a town of Hindustan, province of Gujerat, district of Chalawara. It is of considerable extent and population, and possesses a fort of considerable strength, almost new. It belongs to a rajpoot family noted for their skill and bravery in predatory wars. In 1805 it was besieged for two months without success by the Guicowar's army. It carries on, by means of caravans, an extensive trade with the Gulf of Cambay. These caravans require an escort of twenty to thirty matchlock-men, to guard against the freebooters that infest the country.

WURDA, a river of Hindustan, province of Berar. It has its source in the Injardy Hills, two miles north of the Barooly Pass, in the province of Berar, whence it flows in a south-east direction, and after a course of about 200 miles falls into the Godavery.

WÜRTEMBERG, a kingdom in the interior of Germany, formed, within the last few years, out of the ancient duchy of the same name, with the addition of several smaller territories progressively combined with it, in the reigns of the last two sovereigns, by an accommodating policy, and a sedulous regard to their own interest during the progress and conclusion of the French revolution. By an armistice made with France in 1796, all the territories on the left bank of the Rhine were ceded to that power; but by the opportune peace of Luneville in 1801, and a separate treaty which followed as a consequence of it, Würtemberg was raised to the dignity of a grand duchy, and obtained several districts which had either been portions of small independent states or ecclesiastical dominions. Among these were the cities of Heilbron, Gmünd, Hall, Rothweil, and some others, with the districts around them. The whole of these acquisitions extended over 633 square miles, and contained 115,000 inhabitants. In December 1805, in consequence of the part taken in the war between France and Austria, the kingly dignity was assumed, and the possession of several other portions was guaranteed by the former power. These acquisitions comprehended several districts on the Danube, whose inhabitants were estimated to be 158,000. In 1806, when the confederation of the Rhine was formed, Würtemberg joined it, and stipulated to contribute to its support 12,000 men; in consequence of which, other considerable additions to its territory were made. Several exchanges of dominion took place with Baden and Bavaria, but rather for the sake of rendering the limits more distinct than to increase possessions. The part taken by Würtemberg in the wars declared by France against Prussia in 1806, and against Austria in 1809, led to a further augmentation; and by choosing the precise moment for deserting the cause of Bonaparte in 1813, the king was enabled, at the subsequent congress of Vienna, to obtain the sanction of all the great European powers to the title which he had assumed, and to the territory which had been acquired. The kingdom of Würtemberg was thus fixed in the condition described in the following pages.

The whole is nearly enclosed between Baden and Bavaria; the former bounding it on the western and northern sides, and the latter on the eastern and southern, except that on one part of its southern frontier the Lake of Constance separates it from Switzerland. It is of an irregular form, extending from 47° 35′ to 49° 35′ north latitude. On a very small portion of its northern boundary it comes in contact with the grand duchy of Hesse-Darmstadt. Its whole extent is 7573 square miles, or 4,846,720 English statute acres.

The ancient divisions of the duchy of Würtemberg were various, according to their position and feudal claims; and the additional territories that had been recently acquired were in very irregular and unequal allotments. Of late, a new division has taken place into circles, which are again subdivided into *Oberamts* or bailiwicks. Besides these circles, the capital, the city of Stuttgart, forms by itself a separate division, though its inhabitants are included in the population returns of the Neckar circle.

The circles, with their extent and population, are,

	Extent in Statute Acres.	Population in 1834.
Circle of the Neckar	904,320	442,447
Circle of the Jaxt	1,318,400	349,779
Circle of the Black Forest (Schwarzwald)	1,204,480	414,489
Circle of the Danube	1,468,160	362,999
	4,895,360	1,569,714

By a subsequent enumeration taken at the end of the year 1835, the result, no account of each circle being given, appears to shew that the males of the kingdom were

786,[illegible]9, and the females 825,180, making thus 1,611,799. As the increase of the population seems still to be progres- ive, it may probably at this time (1841) exceed 1,750,000 ersons.

This population is found in 130 cities (having or formerly aving had walls), 128 market-towns, 1115 parishes, 558 amlets, 2591 farms, and 269 castles or seats of the nobi- ty. The increase of population, calculated by the excess f births over deaths, has been about 10,000 on an average f several years.

The inhabitants are partly of Swabian and partly of Fran- onian origin, and retain the peculiar pronunciation of the aces from which they are descended. There are likewise ome settlements of the Waldenses. The Swabians make se of many words very different from the other German eople, and adopt many variations in the idioms not known lsewhere. These may be observed to alter at every ten r twelve miles in travelling through the country.

The prevailing religion in old Würtemberg was the Lu- heran, for which it suffered most severely during the thirty ears war. No toleration was granted to any other sect xcept to the Waldenses, and they were confined within rescribed limits, and even in those spots were under some trict regulations, and excluded from the rights of citizen- hip. Since 1806, the three religious parties have enjoyed he free exercise of their modes of worship, and a partici- ation in all civic rights, with eligibility to all public offices. The Lutherans and Calvinists, now united, are distinguished y the name of the Evangelical Church. Their number n 1833 was 1,087,413, and that of the Romish church 489,[illegible]25. There are many sectaries, such as Separatists, Baptists, Hernhutters, and others, who are neither favoured nor persecuted by the government. Through the whole f protestant Würtemberg there is a great number of per- ons distinguished by the appellation of Pietists, who hold their private meetings for devotion, but do not in other re- pects separate from their churches. The Lutheran church s under the direction of six superintendents, whose dioceses re divided into fifty deaconries, and supplied with 818 pas- ors. The Catholics are governed by a vicar general, who s assisted by a council consisting of clerical and lay mem- ers the priests under them are about 640. The Lu- heran clergy are in general better supported, and taken rom a somewhat higher class of people than in most of the other parts of protestant Germany. The Jews, who have established themselves chiefly in the new provinces of Wür- emberg, amount to about 10,766 persons.

Few parts of Germany have exhibited more or better specimens of knowledge and talent than have been produced rom the institutions for education in Würtemberg. The state has, for its population, more means for acquiring learn- ng. The endowed classical schools are fifty-five, from which the theological pupils are transferred to the univer- sity of Tübingen, where they are maintained from the funds of the institution. In these establishments the pupils are not confined to mere professional pursuits, but have their attention directed to general knowledge. The university of Tübingen has long been considered one of the best in Germany. There are, besides, the gymnasium at Stutt- gart and seminaries for the protestant clergy at Maulbroun, Schönthal, Ulm, Heilbron, and Ochriengen; and for Catholics at Rothenburg, Rothweil, and Ellwang. Schools for instructing the poorer classes of the people are amply provided in every part of the kingdom, so that the knowledge of reading, writing, and arithmetic is almost universal. No village is without its school, and scarcely a market-town without a classical instructor.

The kingdom may be considered as hilly, if not mountainous. On the eastern part is the group of the Swabian Alps, and on the western the Black Forest, a continuation of the Swiss Alps. The highest points of these two groups of elevations are from 2500 to 2800 feet. The eastern are not so lofty as the western ranges of hills, but they are more bleak, raw, and unhealthy. There are no plains, but some extensive and beautiful valleys, highly fruitful, of which that of the Neckar with its branches, and that of the Danube from Tutlingen to Ulm, are the most celebrated. The various smaller valleys, running between the hills, and terminating on the banks of the several rivers, present rich and beautiful prospects. The woods are extensive, and contain almost every kind of forest-tree; but the absence of hedgerows is a great drawback to the beauty of the country in most parts of the kingdom. The scenery is much indebted to the rivers and the several tributary streams which run through all the valleys. The Neckar rises in the southern extremity of Würtemberg, and, with many windings, leaves the kingdom on its northern frontier, in its course to join the Rhine. It collects the waters of the Kocker, the Jaxt, the Rems, the Ens, the Erms, and the Zaber. The Danube rises in this kingdom, from the mountains of the Black Forest, and leaves it at Ulm, on the frontiers of Bavaria. It is increased by the several streams of the Iller and the Brentz. The Tauber, in the north, is one of those streams which contribute to the waters of the Maine. The Schussen and the Argen are two small rivers that empty themselves into the Lake of Constance. That lake borders a small part of the kingdom. The Feder Lake, about three miles in length and breadth, and those of Laufen and Pfaffen, which are smaller, lie within its boundaries.

The land of Würtemberg has been recently classed thus: meadows 640,000, arable 1,620,000, woods and forests 1,520,000, and vineyards 61,000 acres; the remainder is either waste or occupied by the lakes, rivers, cities, and towns. In no part of Germany is so much attention directed to agriculture as in this kingdom, and in no part of it are the practices so generally good. The cultivation of green crops is much diffused. Turnips, but more especially mangel wurzel, are grown to clear the land from weeds, and to a great extent have superseded the former mode of fallowing. Potatoes are very extensively cultivated, and not only form the chief food of the working classes, but are used for the purpose of making brandy, as well as feeding cattle. The rape and poppy plants are grown for making oil; and that which is expressed from the latter is found to be equal, if not superior, for the use of the table, to the oil of olives. Hemp and flax are raised in abundance, the former chiefly in the middle provinces, and the latter most extensively in the district of the Black Forest. The harvests of corn are tolerably productive of wheat, rye, oats, and, in some of the warmer districts, of maize. The supply of grain is estimated for the whole kingdom at about 23,000,000 bushels; of which, as potatoes are extensively used for food, some is every year sent to supply the wants of the neighbouring states. The woods afford more fuel and building materials than are demanded for domestic consumption; and the surplus, by means of the rivers, is conveyed to the countries lower down the several streams. The vineyards produce abundance of wine, and, though generally not of a good quality, and much of it very bad, its culture is found very beneficial. The best wines usually comprehended in the general class of Neckar wine are those made on the hills near the old castle of Würtemberg, at Uhlbach, Fehlbach, Upper and Lower Turkheim, Lichtenberg, Rosswag, Maulbroun, and Tauberthal. The most productive vineyards are those on the western borders of the eastern Alps, where a single acre has been known to yield more than 2000 gallons; but it more resembles vinegar than wine. It is generally remarked that the Neckar wines have much deteriorated of late years; which is attributed to negligence in the choice of the most proper plants, and to attention being principally paid to such as yield much, rather than to such as yield the best wine. The wine made in the year 1811, Würtemberg.

as was the case on the banks of the Rhine, and in most parts of Germany, was of an unusually good quality; and such of it as now remains sells for 300 florins the emir, while the wines of later years are not worth more than 139 florins. The annual value of the wines made in the kingdom on an average is L.400,000 sterling.

The cattle in Würtemberg have been carefully attended to, and the cows especially are of a very good description, which is attributed to the care in improving the breed, and to their being generally stall-fed, or soiled with green food. The butter is excellent, and in many districts good cheese is made, but the last less extensively than with due pains it might be. The sheep have been much improved by constant crossings between the old races of the country and those of the Rousillon and Merino breeds, and now the greater part of the flocks are of the fine-woolled kind. The breed of horses was at one time much improved by the introduction of Holstein and English stallions. Of late years they have been retrograding, but the government has now been induced to take steps, by introducing studs of the best horses, for improving them again. The number of cattle in the year 1820 was thus enumerated: horses 80,870, cows 599,490, sheep 488,940, swine 114,200, goats 16,620, asses 1008. There is however good reason to conclude, from what is known of the prosperous state of the country, that the increase in the live-stock has kept advancing in a degree similar to that of the human beings.

The fisheries are very productive both in the lakes and the rivers. The Lake of Constance affords abundance of salmon trout, perch, carp, and barbel; the other lakes and the rivers yield trout, eels, barbel, pike, and several other kinds of fish; and in the Feder Lake the shad is found of a very large size.

The only mines that are extensively worked are those of iron, at Neuhausen, Fluorn, Neuenberg, Aalen, and Wasseralfingen. The ore from these mines is prepared both by smelting and the hammer, and supplies the manufacturers of Fredicksthal, Christophsthal, Ludwigsthal, Harras, and Heidenheim, with minerals for their cutlery and ironmongery. There are saline springs at Hall, Sultz, Offenau, and Weisbach, from whence are annually made about 8000 tons of culinary salt; and a new spring, lately opened at Kochendorf, promises to afford a more copious supply, so as to dispense with the quantity of that commodity now purchased from the kingdom of Bavaria.

Since the conclusion of war, some valuable mineral springs, before unknown or neglected, have been used for medicinal purposes; and accommodations have been provided in a style of elegance and convenience which attracts to them a great number of visitors in the summer months, when the power of the waters is deemed most efficacious. The principal of these are at Kannstadt, on the right bank of the Neckar, a few miles from Stuttgart. There are more than thirty springs in and about the town. The waters are cold; they contain Glauber, Epsom, and common salts, mixed with a small portion of iron, and are found of great efficacy in curing disorders of the digestive powers. At Wildbad in the Black Forest, nearer to the capital of Baden than to the capital of Würtemberg, the springs are hot, varying from the temperature of 65° to 100° of Fahrenheit. The water is colourless, and has neither taste nor smell, but it gives out much carbonic acid gas. Few ingredients of a medicinal nature have been detected in it; but the use of the baths has been found by experience highly salutary in gouty and rheumatic complaints, and the temperature being nearly the same as that of the human blood, the use of them is highly pleasant to the feelings. The baths are hollows scooped out from the granite rock, some large enough to hold many persons at once, who, however, when bathing in company, have bathing gowns provided for them. The supply of water is so copious that it is constantly flowing, and never allowed to stagnate in the baths. Rippoldsau is also in the Black Forest, and on the confines of Baden, to which duchy it formerly belonged. The accommodations are tolerably settled, and gradually improving, but scarcely yet adapted for more than 150 or 200 visitors. The water is alkali-saline, is pleasant to take as a common drink, and is as effervescent as the celebrated water of the Selzer well.

The chief manufactory of Würtemberg is that of linen. The inhabitants of the eastern Alps and of the Black Forest are employed in this branch of industry. In those districts almost every female is occupied during the winter in spinning, and every peasant is a weaver. Both fine and coarse linen is produced, and also diaper and sail-cloth. In Münsengen there is a manufactory for damask table-linen, which produces most excellent goods. In some parts of the kingdom the females find employment in making a coarse kind of bone-lace. The cloth-manufactures are inconsiderable, and seem to be far from flourishing; and much of the wool clipped within the kingdom is either exported in the raw state, or, after being spun, to the neighbouring countries. Cotton spinning and weaving have been introduced at several places, but those establishments are in a languishing state. Leather, glass, paper, snuff, beer, hardware, cutlery, with oil, pitch, tar, and potash, are all made in different parts of the kingdom. The breweries, and especially the distilleries, are numerous. In the large village of Mossingen there are no less than 280 stills for making brandy and whiskey. This is the country for making wooden clocks; and those works produced in Würtemberg, or from natives of it who have transferred their labour to other countries, are to be seen in almost every part of Europe.

The chief commerce of Würtemberg consists in the exchange of its commodities with the adjoining states. It sells to them 18,000 oxen, 12,000 cows, 75,000 sheep and lambs, and 550,000 lbs. of wool, more than it buys. The usual export of corn beyond the import is 80,000 quarters. The corn exported chiefly consists of rye, most of which is sent to Switzerland from the Würtemberg ports of Frederickshaven and Morsburg, on the Lake of Constance. The other sales include linens, leather, snuff, pitch, tar, potash, oil, and wood, and wooden toys of various descriptions. The imports are silk, cotton, wool, East and West India productions, flax, hemp, hides, and salt. The balance of payments is usually in favour of Würtemberg.

The government of Würtemberg is at present an hereditary limited monarchy. The King is the sole sovereign, and acts without control by his ministers, in every executive department. He appoints to all offices, makes war and peace, commands the forces, distributes rewards, confers dignities and honours, executes justice, and dispenses pardons. Under the ancient dukes, within the original territories of Würtemberg there existed a feudal constitution. The states, consisting of fourteen prelates and seventy-one deputies from the cities, exercised some legislative authority; but on the assumption of the kingly dignity, and the addition of the acquired provinces in 1806, the monarch assumed unlimited power, until the termination of the war, and the end of the congress of Vienna, when a new constitution was promulgated. Two legislative chambers were instituted. The upper was composed of the mediatized princes, the high nobility, and the prelates of the Protestant and Catholic churches; the lower consisted of the deputies from the cities of Stuttgart, Tübingen, Ludwigsburg, Ellwang, Ulm, Heilbron, and Reutlingen, from the learned institutions, and from the several bailiwicks. The privileges of the nobles were thought by themselves to be invaded, and they did not concur in this constitution. Difficulties arose in reducing to practice the project, and how far it may be realized, or how it may eventually work, cannot yet be fully ascertained. The citizens and the peasant enjoy equal rights, and the feudal slavery of the latter is universally abolished. All have equal pretensions to public employments, and all the Christian sects enjoy the same rights. The feudal tenures are destroyed, and the estates formerly subject to them are converted into freehold properties.

The administration is executed by six ministers, whose departments are thus denominated: justice, foreign affairs, domestic affairs, war, finance, and police. Each of these ministers is at the head of the board which regulates his own branch of the executive government. The law is founded upon the ancient feudal principles which prevailed in Würtemberg at the earliest period, but in some instances is tempered by the addition or intermixture of the Roman law. The administration of justice in smaller matters is executed by provincial judges. There are four superior courts for the four circles, and a supreme tribunal of appeal and revision is established at Stuttgart.

The finances of the kingdom are in an improving condition. The income, according to the latest budget, amounted to 10,794,114 florins, of which about 4,000,000 are derived from the royal domains, and the remainder from direct and indirect taxes. The expenditure was 9,150,460, thus leaving a surplus of 1,643,654 florins, which was applied to the payment of the interest and to the reduction of the public debt. That debt has been reduced during the long peace, and now amounts to about 23,000,000 florins, bearing interest at the average rate of four per cent. The florin there is equal to twenty pence sterling. To the honour of the kingdom, it is to be observed, that the expenditure on the church and on education (chiefly for the latter object) is greater than for the war department by 350,000 florins.

The army consists chiefly of what may be called skeleton regiments, and, though now not exceeding 5000 men, can be constantly augmented in case of need to 16,000, by calling into service those on furlough. It would then consist of four regiments of cavalry, eight regiments of infantry, a corps of guards, of horse and of foot artillery, a small corps of riflemen, and another of sappers. The contingent to the German league is fixed at 13,955 men.

The cities whose population exceeds 6000 are the following. Stuttgart, including the military, 35,000; Ulm, 1[illegible]500; Heilbron, 10,500; Reutlingen, 10,400; Tübingen, 7[illegible]0; Esslingen, 6500; Hall, 6300; Ludwigsburg, 6200; R[illegible]thenburg, 6150; Gmünd, 6050.

WÜRZBURG, a large city of Bavaria, formerly the capital of the sequestrated ecclesiastical principality of that name, but now the chief place of a bailiwick to which it gives the name, in the Bavarian province of the Lower Maine. It still retains the name of a grand duchy, and comprehends an extent of nearly 2000 square miles, with a population of about 290,000 souls. The land is for the most part level, but is surrounded with woody mountains on three sides. It is watered by many small streams which flow into the Maine, and ultimately into the Rhine. The soil is fertile, yielding abundance of corn; but the vineyards occupy a great portion of the land very profitably. The best wines are produced near the capital, and are known by the names of Stein wine, or Leisten wine. The district is not rich in minerals, nor has it much manufacturing industry. The city is built on the river Maine, by which it is divided into two parts connected by a bridge. It is surrounded with walls and ditches; and it is defended by the citadel of Marienburg, built on a hill 400 feet high, which overlooks the city. Some of the streets are broad, and contain fine piles of building; but others are gloomy and narrow. The most distinguished edifice is the former episcopal, now royal residence, a building of vast extent, and of some beauty; and the grounds belonging to it are laid out and preserved in good taste. The university was founded after the model of that of Bologna, in 1403, and after suffering much in stormy times, was renewed in 1582; but since that period it has numbered among its professors some of the most eminent men of Germany. The library of the institution contains upwards of 100,000 volumes, and there are also collections of the different branches of natural history, and all scientific helps. Besides the cathedral, Würzburg contains several churches and monasteries. The inhabitants are for the most part Catholics, and in 1834 amounted to 22,674. The chief trade is in wine, and some is carried on in timber. Long. 9. 49. 25. E. Lat. 49. 46. 6. N.

Wycherley

WYCHERLEY, William, a comic writer who occupied a very conspicuous place among the wits of his age, was born about the year 1640. He was the eldest son of Daniel Wycherley, Esq., a gentleman possessed of a considerable estate near the town of Shrewsbury. Wycherley was probably a cavalier by descent, for during the last years of the commonwealth he was sent by his father, at the susceptible age of fifteen, to prosecute his studies in France; a country which an old puritan was not likely to select as the most eligible place of instruction for his offspring. While in France, he passed some time on the banks of the Charente, and was a frequent and acceptable guest of the duke of Montausier; and in compliment to the duchess, the accomplished Julie d'Angennes de Rambouillet, who is celebrated in the letters of Voiture, the young Englishman became a convert to the Romish faith. From the bosom of that infallible church he was afterwards recalled by the eloquence of Dr Barlow; but to what visible communion a man so profligate, both in practice and speculation, belonged, is a matter of no great moment.

Upon the eve of the Restoration he returned to England, and, from Wood's Athenæ Oxonienses, it appears that he lived for some time in the provost's lodge at Queen's College, Oxford, but left that university without being matriculated. He now proceeded to London, and entered himself of the Middle Temple; but if he had acquired in France too keen an appetite for pleasure to submit to academic restraint, it was not probable that he would apply himself with much earnestness to voluntary drudgery. The gayeties of the metropolis soon converted the student of law into a man of wit and gallantry; nor did any one experience less difficulty in assuming that ostentatious profligacy which was regarded as the true badge of loyalty. In 1672 he produced a comedy entitled "Love in a Wood, or St James's Park," which was acted at the Theatre Royal with great applause. Among the admirers of the author's genius was the duchess of Cleveland, the mistress of the king, and one of the most celebrated beauties of her time. Love in a Wood is dedicated to that lady; a compliment for which she manifested the sincerity of her gratitude by the most signal tokens. Dennis relates, that when Wycherley was taking the air in that place of fashionable resort which had given a name to his play, his carriage came in contact with that of her grace, who threw herself half out of the window, and rallied him with a freedom and gayety that cannot well be repeated. The result of this rencontre was, that Wycherley became the successful rival of his sovereign, and incurred the displeasure of the haughty Buckingham. In this emergency, he solicited the good offices of Rochester and Sedley, who had such confidence in his colloquial powers that they hurried him off to sup at the apartments of the duke. The event justified this bold proceeding, for, like a noble bard of modern times, who should have been the contemporary of his grace, he was always most "strongly acted on by what was nearest;" and after some irresistible sally of his guest, he exclaimed with an oath, "My cousin's in the right on't!" But Charles could be as fickle as herself.

"This year, 1672," says Burnet, "the king declared a new mistress, and made her duchess of Portsmouth."

He now rose to high favour with Buckingham, who, as master of the horse, appointed him one of his equerries, and, as colonel of a regiment, captain-lieutenant of his own company. He is likewise said to have conferred upon him many other advantages. But the poet had not yet reached the height of his good fortune. His next patron was the merry monarch himself, who thought no reward too great for a jest, and no recompense too inconsiderable for those who had shed their blood in his service. Such devotion indeed was strongly indicative of folly, and Charles admired none but men of wit. Wycherley was fortunate enough to inspire the king with excessive fondness, which was crowned by the very singular condescension of paying him a visit at his lodgings, when he was ill of a fever. When he became somewhat convalescent, his majesty advised him to try the air of Montpellier, and furnished him with five hundred pounds to defray his travelling expenses.

In 1673 was acted at the Duke's Theatre Wycherley's second comedy, "The Gentleman Dancing-Master." The incidents of this play are quite farcical, and the catastrophe is obvious from the commencement. It appears to have been coldly received, for in the prologue to his next comedy, the Country Wife, occurs the following line:

> The late so baffl'd scribbler of the day.

"The Country Wife" was acted in 1675, and was followed in 1677 by "The Plain Dealer." Wycherley's first play made him the paramour of a woman who wanted only the name of a queen, and his last made him the husband of a countess. Being on a visit to Tunbridge, he entered a bookseller's shop, and while he remained there a lady came and inquired for the Plain Dealer. "There he is for you, Madam," said a friend of his, one Mr Fairbeard, by whom he was accompanied, pushing Wycherley towards her. This lady was the countess of Drogheda; and an acquaintance, thus ludicrously commenced, soon ripened into an intimacy that terminated in a matrimonial union. Wycherley's splendid marriage was the most disastrous incident of his life. His lady's outrageous jealousy, for which it was not improbable that he gave her some cause, imbittered his existence, for she became infuriated whenever he disappeared from her sight. Sometimes, by special favour, he was permitted to dine at the Cock Tavern, opposite their lodgings in Bow Street; but upon these occasions he was compelled to leave the windows open, that she might be satisfied there was no woman present. She did not live long to torment him, and left him her whole fortune at her death; but her will was contested, and he found himself heir to nothing but a suit at law. Being unable to pay the expenses of litigation, and some other debts which he had contracted when he thought himself beyond the reach of poverty, he was thrown into a jail, where he was suffered to languish for the space of seven years. From giddy splendour to unpitied destitution there was an easy and natural transition. To the king it is not likely that he had the assurance to apply; but his father would do nothing for him, and he was refused a loan of twenty pounds from his bookseller, who had made large sums of money by his works. From this abyss of misery he was rescued at last by a hand that was soon afterwards deprived of the power to do either good or evil. Charles was now dead, and his luckless successor happening to see the Plain Dealer acted, was touched with compassion for its author, and assigned him a pension of two hundred pounds a year.[1] He also gave orders for the immediate payment of his debts, and sent Lord Mulgrave to ascertain their amount; but Wycherley was ashamed to tell that nobleman how much he owed. He was now restored to liberty, but continued to be harassed by his creditors till near the close of his life, when he devised an expedient to satisfy their demands, which at such a solemn crisis could scarcely have occurred to any one but himself. By the will of his father, to whom he seems to have owed little but his birth, he was deprived of the power of alienating the family estate; and not wishing to quit the world in debt, a feeling which deserves commendation, he married a young woman possessed of fifteen hundred pounds.[2] With odious indelicacy, this creature was induced to give her hand to the expiring debauchee by the inducement of a handsome jointure. Having discharged his other debts with part of his wife's fortune, he paid the debt of nature on the 1st of January 1715, eleven days after the celebration of his nuptials. A little while before he closed his eyes for the last time, he is said to have requested his wife, with Cervantic gravity, not to take an old man for her second husband. Thus was a life of frolics closed with perfect consistency. Major Pack says that he died a papist. He was a great admirer of Dryden, in whose honour he wrote some indifferent verses: perhaps the melodious reasoning in the Hind and Panther had some share in the merit of his reconversion to the Romish faith.

Wycherley is eminent only as a writer for the stage, but he is the author of a large volume entitled "Miscellany Poems, as Satyrs, Epistles, Love-Verses, Songs, Sonnets, &c." Lond. 1704, fol. The times had changed since Charles's days, but Wycherley continued the same. The public ear had become habituated to gracefully-expanded sentiments which he wanted the skill to supply, and if not to more severe morality, to less inharmonious impurity than his; and the dissonant and licentious crudities of the veteran rake excited little attention. The versification of Wycherley is scarcely more felicitous than that of Dr Donne. Several years after his death appeared "The Posthumous Works of William Wycherley, Esq. in prose and verse: faithfully publish'd from his original manuscripts, by Mr Theobald. In two parts. To which are prefixed, some Memoirs of Mr Wycherley's life, by Major Pack." Lond. 1728, 8vo. By appealing to the avarice of one Captain Shrimpton, who had married his relict, the booksellers obtained the possession of the papers which formed this collection, in which there is nothing that can add to the reputation of Wycherley, either in a moral or intellectual point of view. His folio volume is curious, as containing the pieces alluded to in the following passage in Johnson's Life of Pope: "His esteem of Pope was such that he submitted some poems to his revision, and when Pope, perhaps proud of such confidence, was sufficiently bold in his criticisms and liberal in his alterations, the old scribbler was angry to see his pages defaced, and felt more pain from the detection than content from the amendment of his faults. They parted; but Pope always considered him with kindness, and visited him a little time before he died."[3] Lady M. W. Montagu says that Pope paid his court to him with a view to a legacy; but this calumny is sufficiently refuted in the state of Wycherley's affairs. At this period Pope was about sixteen, and Wycherley had passed his grand climacteric.[4]

---

[1] Among his Posthumous Works is a poem "On a Sea Fight which the author was in, betwixt the English and Dutch," p. 235. James's kindness for him may have been prompted by the remembrance of mutual danger. It is possible that Wycherley served under him upon one or other of the occasions when he commanded the red squadron against the Dutch. Some nautical knowledge, however acquired, is displayed in the Plain Dealer.

[2] For this act another motive has been assigned, the wish to disinherit a nephew whom he disliked.

[4] The letters that passed between Pope and Wycherley are to be found in Warton's edition of Pope's Works, vol. vii. p. 1–52.

WYCLIFFE, John, who was born about the year 1324, der ed his name from the place of his nativity, a village six iles from Richmond in Yorkshire. From the era of the Norman conquest, the family to which he is supposed to h ve belonged had been lords of the manor, and patrons of t e rectory of Wycliffe ; and it is to be inferred that his par nts were able and willing to give him the best education which the kingdom then afforded. In due time he becam a commoner of Queen's College, Oxford, a seminary of ery recent institution ; but he speedily removed to Me on College, which then enjoyed a higher reputation tha any other house of learning: the scholastic celebrity of uns, Ockham, and Bradwardine, was alone sufficient to onsecrate its walls. Having been duly initiated in logic nd rhetoric, he directed his attention to other branches of owledge. His proficiency in the civil, the canon, and the municipal law, has been noticed by Lewis, and oth biographers; but his greatest efforts were devoted to the study of theology, not merely that barren art which was then taught in the schools, but that divine science wh h is derived from the spirit as well as the letter of the Sc tures. In the prosecution of his inquiries, he had to co end with numerous and formidable difficulties: the gen s of the age was hostile to any plan of study or mode of vestigation which the church had not sanctioned ; the tex of the sacred writings was in a great measure neglected, while its place was supplied by systems of scholastic div ity; the original language of the New, as well as the Ol Testament, was almost totally unknown in the kingdom; the inhabitants of the western world had almost universally surrendered their understanding to the control of a b dy of priests, who reduced spiritual tyranny and delusio to a complete system; and the student eagerly bent on e search of divine truth, was left without encourageme t and without a guide. But in spite of all these disadva ages, Wycliffe pursued his course with alacrity and per everance. He arrived at a degree of scriptural knowled e which had not been equalled for many centuries ; an his veneration for the sacred writings procured him the honourable appellation of the Evangelic Doctor.

is earliest publication, entitled " The last Age of the Ch rch,"[1] appeared in 1356, when he is conjectured to have att ned the age of thirty-two. In 1347, England had be visited by a pestilence, which first made its appearan in Tartary, and after ravaging various countries of As , proceeded by the shores of the Nile to the islands of Gr ece, and carried devastation to almost every nation of Eu ope. So prodigious was the waste of human life, that thi quarter of the globe is supposed to have lost a fourth pa of its inhabitants.[2] The direful distemper was even commu icated to the brute creation, and the land was covered wi putrid carcasses. These portentous signs of the tim s filled the pious mind of Wycliffe with gloomy apprehe ions, and led him to indulge in speculations respecting the ast age of the church. He arrived at the conclusion th the day of judgment was not to be deferred beyond the close of the century in which he himself lived. Many ind viduals of a visionary turn of mind, and some possessed of e most vigorous understanding, have in various ages ha rded similar predictions. It is stated by Dr Vaughan, th " the opinions and the feeling disclosed in this produ ion, though but imperfectly developed, are such as to pr are the reader to anticipate in Wycliffe a devout oppo ent of the corruptions which it describes with such sole nity and pathos. It is important to know, that even at th period of his history, the nefarious practices connected wi the appointment of the clergy to the sphere of their duties, had so far shocked his piety, as to dispose him to expect a speedy and signal manifestation of the displeasure of heaven." After an interval of a few years, he distinguished himself by his strenuous opposition to the mendicant orders, who then infested the best parts of Europe, and, under the pretext of betaking themselves to a life of poverty and devotion, consumed the fruits of the earth, and too often set an example which did not tend to edification. In 1360 he published his Objections to the Friars, which were long afterwards committed to the press by Dr James. The errors and vices of the mendicants, it has been remarked, had never been so generally or so forcibly assailed ; and while those who preceded aimed only at the removal of particular abuses, he perceived that the institution itself was unnecessary and pernicious. The friars were a class of men whom it was dangerous to provoke ; nor is it to be doubted that he thus made a large addition to the catalogue of his enemies. His friends however were likewise numerous. In 1361 the society of Balliol College presented him to the rectory of Fillingham, in the diocese of Lincoln ; and he became master of that college in the course of the same year. In 1368, he exchanged this living for Lutgershall, in the archdeaconry of Bucks ; a benefice of inferior value, but situated at a more convenient distance from Oxford. After retaining his mastership for the space of four years, he was appointed warden of Canterbury Hall, recently founded in the same university by Simon Islep, archbishop of Canterbury, with a provision for twelve scholars, eight of whom were to be secular clerks, and the remaining four, including the warden, were to be chosen from the monks of Christ Church, Canterbury. The warden first nominated by the founder, was one Wodehall, a fierce and turbulent monk, whom he soon found it necessary to remove from his office. Wycliffe was invited to supply his place, and the archbishop did not long survive. His successor in the primacy was Langham, bishop of Ely, who had previously been abbot of Westminster, and still retained the spirit of a monk. Wodehall appealed to this new visitor, and found the support which he expected. The appointment of Wycliffe having, with little regard to law or fact, been pronounced null and void, a person named Radyngate was first substituted in his place, and in the course of a few weeks Wodehall resumed the office of warden. From this arbitrary sentence, Wycliffe appealed to the sovereign pontiff; and, after an interval of several years, found it was vain to expect that justice should flow from so polluted a fountain. The decision of the pope was confirmed by the authority of the king, who did not however pronounce an unbribed judgment.

About the time when Wycliffe was appointed warden of Canterbury Hall, a controversy had arisen between Urban the Fifth and Edward the Third, in consequence of the renewed demand of an annual tribute of a thousand marks, as an acknowledgment of the feudal superiority of the pontiff over the kingdoms of England and Ireland. The payment of this degrading tribute had never been regular, and it had been entirely discontinued for thirty-three years; but on the renewal of the papal claim, the king thought it necessary to consult both houses of parliament. " The prelates solicited a day for private deliberation; but assembling on the morrow, the lords spiritual and temporal, and the members of the commons, were unanimous in stating, that neither King John, nor any other sovereign, had power thus to subject the realm of England, without consent of parliament; that this consent was not obtained; and that, passing over other difficulties, the whole transaction, on the part of the king, was in violation of the oath which he had taken on receiving the crown. By the temporal nobility, and the popular representatives, it was farther determined, that should the pontiff commence his threatened process against the monarch of England, as his vassal, the strength of the nation should be instantly called to the king's aid."[1] But the most gross and scandalous usurpations will always find a sufficient number of defenders, when the usurpers have the power of bestowing a sufficient number of rewards. The claims of the pope were maintained by some nameless monk, who on this subject published a tract, in which he called upon Wycliffe to refute his arguments. In this appeal to him by name, we discover an obvious proof that his character had already become very conspicuous; and although it was apparently the writer's intention to do him an injury rather than an honour, he did not decline the challenge which had thus been given. He published a work in which he endeavoured to circumscribe the arrogant claims of the church, and to fix the legitimate extent of civil authority: he maintained the right of the king and his parliament to refuse the tribute claimed by the court of Rome, to subject all ecclesiastics to the secular jurisdiction in all civil cases, and even to alienate the property of the church. Some of his opinions are so much at variance with the doctrines of the canon law, that he had evidently made no inconsiderable progress in his retrograde motions from the popish standard of orthodoxy.

---

[1] The last Age of the Church, by John Wycliffe : now first printed from a manuscript in the University Library, Dublin. Edited, with no , by James Henthorn Todd, D. D., &c. Dublin, 1840, sm. 4to.

[2] The Black Death in the fourteenth Century, from the German of I. F. C. Hecker, M. D., translated by B. G. Babington, M. D., p. 77. Lo . 1833, 12mo. " It may therefore be assumed, without exaggeration, that Europe lost during the Black Death 25,000,000 of inhabitants."

The question respecting the wardenship was finally decided in the year 1372, when the king confirmed the sentence of the pope. Wycliffe now found other employment in the university. Having taken the degree of D. D., says Lewis, he " publickly professed divinity, and read lectures in it; which he did with very great applause, having such an authority in the schools, that whatever he said was received as an oracle. In these lectures he frequently took notice of the corruptions of the begging friars, which at first he did in a soft and gentle manner, till finding that his detecting their abuses was what was acceptable to his hearers, he proceeded to deal more plainly and openly with them." It is more than probable that the influence which he exercised over his own age, is in some degree to be ascribed to the circumstance of his occupying a theological chair in this university, which about that period was frequented by a great multitude of students. The invention of printing had not yet afforded the means of disseminating knowledge with great facility, and with great rapidity: books, which could only be multiplied by the slow process of transcription, were necessarily sold at a high price; and the number of individuals capable of reading them was surprisingly small. But the voice of the public teacher was raised with living energy; and his opinions, inculcated with learning and fervour, could not fail to influence those who in their turn were to become public teachers.

In the year 1374, he was employed in an embassy to the pope, Gregory the Eleventh, whose residence was at Avignon. The first person named in the commission is the bishop of Bangor, and the second is Dr Wycliffe. Their mission had a reference to one of the flagrant abuses of that period, the papal reservation of benefices in the English church. The ecclesiastical revenues, to a very great amount, were appropriated in this manner, and in many instances were most unworthily bestowed upon foreigners who were entirely unacquainted with the language of the country, and who were sometimes of too tender an age to be intrusted with the cure of souls. Against this branch of pontifical usurpation, the statute of provisors had been enacted in the year 1350. The embassy was not received at Avignon, but at Bruges; and with most of the pontiffs it would have been an act of wisdom to keep all strangers at a distance from their ordinary place of residence, which was too commonly the fountain-head of all iniquity. John of Gaunt, duke of Lancaster, had at the same period repaired to Bruges on another diplomatic mission; nor is it improbable that Wycliffe may thus have had a favourable opportunity of recommending himself to his powerful protection. The duke, as Dr Vaughan has remarked, is " the only son of Edward the Third, whose name is connected with the religion of that period, and who is known as the patron of Chaucer and Wycliffe." It is not certain that the latter returned to England before the year 1376; but in the mean time he received different marks of the royal favour. He had formerly been nominated one of the king's chaplains. In the month of November 1375, the king presented him to the prebend of Aust, in the collegiate church of Westbury, in the diocese of Worcester, and about the same period to the rectory of Lutterworth in Leicestershire, the presentation to this benefice having devolved upon the crown, in consequence of the minority of the patron, Lord Ferrars.

Wycliffe had now risen to high distinction, and if his views had been directed to the ordinary objects of a mere churchman's ambition, it is probable that he might have obtained much higher preferment. Many individuals of the middle classes were gradually added to the number of his converts; nor was the duke of Lancaster the only man of rank and influence who regarded his person and doctrines with a favourable eye. But his proceedings must for a long time have excited the watchful jealousy of those who enjoyed the principal emoluments of the church, and were suspicious of all spiritual innovations, lest they might eventually lead to some encroachment on their own temporalities; for it has been remarked in every age, that those well-beneficed clergymen who, by the general tenor of their conduct, indicate the most perfect indifference as to the vital interests of religion, are yet the most loud and vehement in proclaiming the danger to which their " excellent establishment" must be exposed by the slightest change or concession. Being accused of heresy, he was summoned to appear before the convocation, which commenced its sittings in the month of February 1377, and in which Courtenay, bishop of London, made the most conspicuous figure. This prelate was son to the earl of Devonshire, by a grand-daughter of Edward the First, and added the pride of royal descent to the arrogance of priestly elevation. Wycliffe made his appearance at St Paul's on the 19th of the same month, and, to the no small dissatisfaction of the bishop and his partisans, was accompanied by the duke of Lancaster, and by Lord Percy, earl-marshal of England. So great was the concourse of people, that it was not without considerable difficulty that the marshal could procure him an avenue to the presence of his judges, Archbishop Sudbury, and other prelates, who were assembled in our Lady's chapel, behind the high altar. " Dr Wicliffe, according to custom, stood before the commissioners, as one cited to appear there to hear what things they had to lay to his charge; but the earl-marshal, out of tenderness for Dr Wicliffe, and having but little regard to a court which owed all its authority to a foreign power, bid him sit down, telling him he had many things to answer to, and therefore had need of a soft seat to rest him upon during so tedious an attendance. The bishop of London, hearing that, answered, ' he should not sit there;' for, says he, ' it is neither according to law nor reason, that he who was cited here to answer before his ordinary, should sit downe during the time of his answer;' adding, ' that if he could have guessed that the earl-marshal would have played the master there, or been so troublesome, he would not have suffered him to come into the court.' On which many angry words passed betwixt the bishop and the earl-marshal. The duke of Lancaster took the earl-marshal's part, and told the bishop that 'the earl-marshal's motion was but reasonable, and that as for him, who was grown so proud and arrogant, he would bring down the pride, not only of him, but of all the prelacy of England; that he depended upon the greatness of his family, but that they should have enough to do to support themselves."[1]

---

[1] Vaughan's Life and Opinions of John de Wycliffe, D. D., vol. i. p. 280, second edition. Lond. 1831, 2 vols. 8vo. See the Edinburgh Review, vol. li. p. 221.

The duke of Lancaster did not then stand high in the popular favour; and his magnificent palace of the Savoy was attacked during the tumults which followed this stormy discussion. A clergyman, who had the misfortune of being mistaken for Lord Percy, was put to death by the populace. The decease of the aged king ensued on the 21st of June 1377, and he was succeeded by his grandson Richard, who had not completed the twelfth year of his age. A parliament was summoned soon after his accession, and the subject of the papal encroachments was again resumed. By this parliament, a question was submitted to the judgment of Wycliffe, whether a kingdom might not, in a case of necessity, prevent its treasures from being conveyed to a foreign country, although it should even be demanded by the pope himself. Here we have a sufficient proof that the charge of heresy, however it might expose him to resentment from the rulers of the church, had not diminished his credit with the rulers of the state. What answer the professor of divinity returned to this question, no reader can fail to anticipate. His opinions as to the temporalities of the church must have been thought fully as dangerous as his theological doctrines; and on the same day no fewer than four different bulls had been issued against him by Gregory the Eleventh; three of which were directed to the archbishop of Canterbury and the bishop of London, and a fourth to the chancellor and university of Oxford. All these documents, together with an apostolical epistle addressed to King Edward on the same subject, are dated on the 22d of May. The bulls of this "servant of the servants of God," enjoin the parties to whom they are addressed to commit John Wycliffe to prison, and, having transmitted to Rome a full account of his heretical tenets, to detain him in custody until they should receive further instructions; but should they fail in their endeavours to seize his person, they are required to affix in suitable places a citation for his appearance before the pontiff within three months from the date of such citation. These pastoral mandates were not however very effectually executed; but during the earlier part of the year 1378, he appeared before a meeting of papal delegates in the archiepiscopal chapel at Lambeth. His doctrines were rapidly extending their influence, not merely among the people, but even at court. The populace were now alarmed for his personal safety, and, having surrounded the chapel, many of them forced their way into it, and gave sufficient indications of the part which they were prepared to act; nor was the mortification of the delegates diminished by the appearance of Sir Lewis Clifford, who, in the name of the queen mother, the widow of the Black Prince, prohibited them from proceeding to any definite sentence respecting the doctrine or conduct of Wycliffe.

He therefore returned to his former occupations, and by his pulpit discourses, his academical lectures, and his various writings, laboured to promote the cause of truth. The great and glorious labour of his declining years was his complete version of the Bible. It has always been one of the chief arts of priestcraft to keep mankind in a state of ignorance; and it may easily be conceived that an attempt to render the sacred books intelligible to every person capable of reading his mother-tongue, could not fail to kindle the fiery rage of the old Red Dragon. In our own time, we have heard divers denunciations from high-churchmen as to the danger of circulating the Bible without the Book of Common Prayer. According to their estimate, it is better to withhold the one, unless it can be duly qualified by the other. Are we then to conclude that there is no safety beyond the precincts of their own church; that the religion of protestants is only a safe way to salvation, when that way is paced in certain trammels, and swept with a white surplice? Or is the spiritual improvement of mankind of real importance in so far only as it may be circumscribed within the boundaries of episcopacy? The spirit of popery is not confined to professed papists. To translate the Bible was in Wycliffe regarded as an act of heresy, and his version continued to be a proscribed book till the era of the Reformation. Being ignorant of the Hebrew and Greek languages, which he had no opportunity of learning, he was under the necessity of translating from the Vulgate.[2] What aid he may have received from others in the prosecution of his laborious undertaking, it is impossible to ascertain; but it is commonly understood that he was not without coadjutors. In a theological point of view, the value of his translation is far from being inconsiderable, and its value is still more conspicuous in illustrating the history of the English tongue. Wycliffe may indeed be regarded as the father of English prose. His version affords a very ample specimen of the language, as it existed in the fourteenth century; nor is it a little curious to remark, in very many instances, how immaterially his phraseology differs from that of the authorized version executed in the reign of King James. Of his translation of the New Testament, an edition was published by Mr Lewis in the year 1731, and another by Mr Baber in the year 1810; but it is not very creditable to his countrymen, who have derived so much benefit from his pious labours, that his translation of the Old Testament still remains in manuscript. This great deficiency however is at last to be supplied: Mr Forshall and Sir Frederic Madden, both of the British Museum, are now engaged in preparing an edition, which is to issue from the university press at Oxford. Of the influence of Wycliffe's biblical labours, no person seems to have obtained a clearer view than Dr Lingard. He made, says this historian, "a new translation,[3] multiplied the copies with the aid of transcribers, and by his poor priests recommended it to the perusal of their hearers. In their hands it became an engine of wonderful power. Men were flattered with the appeal to their private judgment; the new doctrines insensibly acquired partisans and protectors in the higher classes, who alone were acquainted with the use of letters; a spirit of enquiry was generated; and the seeds were sown of that religious revolution, which, in little more than a century, astonished and convulsed the nations of Europe."

Wycliffe had at first exposed the discipline of the church, and the scandalous lives of churchmen; but he at length raised his voice against several of its doctrines, and particularly against the doctrine of transubstantiation. Wherever the understanding of mankind can be so completely debased as to admit this portentous doctrine, the dominion of the priest must be absolute: he is thus invested with a creative power; after the admission of such a dogma, no other can be found of very hard digestion; and he who exercises so much influence over a future world, must not be left without an ample share of what belongs to this. A persecution was again excited against the reformer; and the duke of Lancaster, who had hitherto befriended him, and who was well aware of the secular corruptions of the clergy, was not however prepared to support him in his attack on what was considered as a fundamental doctrine of the church. Courtenay, who had now become archbishop of Canterbury, was endowed with the spirit of an inquisitor, and appears to have wanted no inclination to confer upon Wycliffe the honour of martyrdom. This venerable man was summoned before a convocation held at Oxford; but although he made no recantation of his supposed errors, they did not venture to treat him as an obstinate heretic. A letter was however procured from the king, commanding him to banish himself from the university. About the same period, he was cited to appear before the pope; but, in return, he gave his holiness some salutary advice, and informed him that he neither felt strength nor inclination for so long a journey. His constitution was indeed exhausted by his multifarious exertions, and he had already been affected with a paralysis, which at length proved fatal. But after his final retirement to Lutterworth, he still continued to labour in the same great cause. He died on the last day of December 1384, when, according to the computation of his biographers, he had attained the age of sixty.

---

[1] Lewis's History of the Life and Sufferings of the reverend and learned John Wicliffe, D. D., p. 53. Lond. 1720, 8vo. See however p. of the last edition, Oxford, 1820, 8vo, which contains various additions.

[2] Jablonski has described Wycliffe as "vir excellenti ingenio, magno animo, et pietate solida præstans, sed quem linguarum sacrarum peritia, literarumque elegantiorum studia deficiebant." (Institutiones Historiæ Christianæ, tom. i. p. 329.)

[3] From the researches of Mr Baber, who has bestowed much attention on the subject, it clearly appears that no entire translation into the English language had preceded that of Wycliffe. This editor has prefixed memoirs of the translator, including a long catalogue of his works. See likewise Dr Vaughan's Life of Wycliffe, vol. ii. p. 379.

The grain of mustard-seed which was now sown became a great tree. The doctrines which Wycliffe propagated with so much zeal and ability, could not again be suppressed: the seat of Antichrist was gradually shaken from its old foundation; and the impulse which he gave to religious enquiry is apparently destined to reach the distant ages of futurity. His theological opinions cannot be detailed in this brief and imperfect notice. It may however be remarked, that he clearly anticipated the most distinguishing doctrines of the protestants, and that his opinions on certain points present an obvious coincidence with those of Calvin. Of the simplicity of primitive times, he was too devoted an admirer to secure the unqualified approbation of modern churchmen; and one biographer is not a little scandalized, because it seems perfectly clear that he did not consider the episcopal order as at all essential to the legitimate constitution of a Christian church. We find Wycliffe "zealously inculcating the lessons of inspiration on the fall of man, and the consequent depravity of human nature; on the excellence and perpetual obligation of the moral law; on the exclusive dependence of every child of Adam, for the remission of his sins, on the atonement of Christ; and for victory over temptation, and the possession of holiness, on the aids of divine grace." We have already had occasion to state, that the influence of his opinions extended to persons of various ranks and denominations. Lord Cobham, the most illustrious of his followers, sealed his testimony with his blood, and many individuals of inferior condition were likewise brought to the stake. The religion of the people was to be purified by fire and fagot; and Henry the Fifth, endeavouring to atone for the follies of his youth by the bigotry of his manhood, rendered himself a willing instrument of persecution in the hands of an unholy and unrelenting priesthood.

The influence of Wycliffe's doctrines soon extended from England to the continent, and their connexion with the subsequent progress of the reformation may very easily be traced. The next conspicuous stage was the kingdom of Bohemia. The king of Bohemia's sister was the consort of Richard the Second, and she came to England in the year 1382. She was a religious princess, and constantly studied the four gospels in English, explained by the expositions of the doctors. The Bohemians who had frequented her court, returned to their own country, and carried along with them some of the works of the great reformer, which, being written in Latin, were intelligible to the learned of all the European nations. Jerom of Prague, who had studied in the university of Oxford, is said to have translated many of his works into the Bohemian language; but, according to another and a more probable account, he only copied some of them in England, and carried the transcripts to Bohemia.[1] By this eminent person, and by his pious leader John Huss, the writings and character of Wycliffe were held in the highest veneration; and they endeavoured to follow his footsteps, by contributing to remove the corruptions of the church. Their earthly career was however terminated in a more tragical manner. The council of Constance, which condemned them both to the flames, added gross perfidy to inhuman cruelty, by violating the safeconduct which Huss had obtained from the emperor Sigismund, and which that prince had not the honour or the resolution to enforce.[2] The same council, a miserable assemblage of those who acted as the representatives of the Christian community, pronounced sentence of condemnation on the whole of Wycliffe's writings; and having decided that he had died an obstinate heretic, and that his memory should be held as infamous, they further decreed that his bones, which had now reposed in the dust for the space of thirty years, should be removed from consecrated ground, and scattered on the dunghill. But the cardinals, archbishops, bishops, abbots, and doctors, who were permitted to play such fantastic tricks before high Heaven, are themselves mingled with the vilest earth, while the name and memory of John Wycliffe continue to be held in unimpaired veneration. (x.)

WYCOMBE, Chipping or High, a market-town of the county of Bucks and hundred of Desborough, twenty-nine miles from London. It is a well-built town, pleasantly situated on a brook which joins the Thames at Marlow, but near Wycombe turns the wheels of several paper-mills, and of others for grinding corn. It is incorporated under a mayor, four aldermen, and eleven councillors. A good market is held on Friday. The population amounted in 1821 to 5599, and in 1831 to 6299.

WYE, a town of the county of Kent, in the lathe of Scray and hundred of the same name, fifty-five miles from London. It stands on the river Stour, and had a market, which has of late years been discontinued. The population amounted in 1821 to 1508, and in 1831 to 1639.

Wye, a river of South Wales, which, issuing out of Plinlymmon Hill, very near the source of the Severn, crosses the north-east corner of Radnorshire, giving name to the town of Rhyadergowy (Fall of the Wye), where it is precipitated in a cataract; then flowing between this county and Brecknockshire, it crosses Herefordshire, and dividing the counties of Gloucester and Monmouth, falls into the mouth of the Severn below Chepstow. The romantic beauties of the Wye, which flows in a deep bed, between lofty rocks clothed with hanging woods, and here and there crowned by ruined castles, have employed the descriptive powers of pen and pencil.

[1] Lenfant, Hist. du Concile de Constance, tom. i. p. 110. Gilpin, who is not very critical in his enquiries, has stated that "he translated many of them into his native language, having with great pains made himself master of the English." (Lives of John Wickliff, and of the most eminent of his Disciples, Lord Cobham, John Huss, Jerome of Prague, and Zisca. Lond. 1765, 8vo.)

[2] If the reader has any inclination to see how perfidy and cruelty can be justified by a true Jesuit, we beg leave to refer him to the elaborate publication of Heribertus Rosweydus, "De Fide Hæreticis servanda ex decreto Concilii Constantiensis Dissertatio cum Daniele Plancio, Scholæ Delphensis Moderatore; in qua, quæ de Husso Historia est excutitur." Antverpiæ, 1610, 8vo.

WYE is also the name of a river in Derbyshire, which rises in the north-west part, above Buxton; and, flowing south-east, falls into the Derwent below Bakewell.

WYMONDHAM, a market-town of the county of Norfolk, in the hundred of Forehoe, 100 miles from London, and nine from Norwich. It is pleasantly situated, and has a church formed out of the ruins of an old Benedictine convent. It has a market on Friday. The population of the whole parish, comprehending six divisions, amounted in 1821 to 4708, and in 1831 to 5484.

WYNAAD, a district of Hindustan, province of Malabar, situated between the 11th and 12th degrees of north latitude, and comprehending an area of 1250 square miles. It is mountainous, and overrun with wood. It is now included in the Malabar collectorship. Its immediate ruler is a Nair chieftain, now tributary to the British.

WYNDHAM, SIR WILLIAM, descended of an ancient family, was born about the year 1687, and succeeded young to the title and estate of his father. On his return from his travels, he was chosen member for the county of Somerset, in which station he served in the three last parliaments of Queen Anne, and as long as he lived. After the change of the ministry in 1710, he was appointed secretary at war; and in 1713 was raised to be chancellor of the exchequer. Upon the breach between the earl of Oxford and Lord Bolingbroke, he adhered to the interests of the latter. He was removed from his employment on the accession of George I., and falling under suspicion on the breaking out of the rebellion in 1715, was apprehended. He made his escape; a reward was published for apprehending him; he surrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in opposition to the several administrations under which he lived, and died in 1740.

WYRA GHUR, a town of Hindustan, province of Gundwaneh, formerly tributary to the rajah of Nagpore. Long. 80. 56. E. Lat. 20. 31. N.

X.

X, or x, is the twenty third letter of our alphabet, and a double consonant. It was not used by the Hebrews or ancient Greeks; for as it is a compound letter, the ancients, who used great simplicity in their writings, expressed this letter by its component letters *c s*. Neither have the Italians this letter, but express it by *ss*. X scarcely begins any word in our language but such as are of Greek origin; and is in few others but what are of Latin derivation, as *perplex*, *reflexion*, *defluxion*, &c. We often express this sound by single letters, as *cks*, in *backs*, *necks*; by *ks* in *books*, *breaks*; by *cc* in *access*, *accident*; by *ct*, in *action*, *unction*, &c. The English and French pronounce it like *cs* or *ks*; the Spaniards like *c* before *a*, viz. *Alexandro*, as it were *Alecandro*. In numerals it expresses 10, whence in old Roman manuscripts it is used for *denarius*; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus, $\overline{X}$, it signifies 10,000.

XATIVA, a government of Spain, in the kingdom of Valencia, extending from the river Alcia to the shores of the Mediterranean Sea. It is now more commonly called St Felipe, its ancient name having been changed by law since the expulsion of the Moors. The capital of the partido of the same name was founded by the Romans, and called by them Setabis. It is situated on the declivity of a calcareous mountain, overlooking a plain not very fruitful, though watered by the river Albayda, one of the tributary streams of the Xucar. The city is surrounded with ancient walls, partly of Roman and partly of Moorish construction, on which are thirty towers. It has also double ditches, and a strong citadel; but all have alike fallen into decay. It is supplied with water by two ancient aqueducts. Before the recent changes, this city contained four parish churches, thirteen monasteries, nine chapels, and eight poor-houses or hospitals. The inhabitants are estimated at 14,000 souls, some of whom are employed in making linen and silk goods, and some writing paper. Near to it are twenty-two warm medicinal springs of various curative power. This place gave birth to a celebrated painter named Ribero, but better known by the assumed name of Spagnoletto.

XEBEC or ZEBEC, a small three-masted vessel, navigated in the Mediterranean Sea, and on the coasts of Spain, Portugal, and Barbary. See SHIP-BUILDING.

XENOCRATES, a celebrated ancient Grecian philosopher, was born at Chalcedon in the ninety-fifth Olympiad. At first he attached himself to Æschines, but afterwards became a disciple of Plato, who took much pains in cultivating his genius, which was naturally heavy. His temper was gloomy, his aspect severe, and his manners little tinctured with urbanity. These material defects his master took great pains to correct, frequently advising him to sacrifice to the Graces; and the pupil was patient of instruction, and knew how to value the kindness of his preceptor. As long as Plato lived, Xenocrates was one of his most esteemed disciples; after his death he closely adhered to his doctrine; and in the second year of the 110th Olympiad, he took the chair in the academy, as the successor of Speusippus. Xenocrates was celebrated among the Athenians, not only for his wisdom, but likewise for his virtues. So eminent was his reputation for integrity, that when he was called upon to give evidence in a judicial transaction, in which an oath was usually required, the judges unanimously agreed that his simple asseveration should be taken, as a public testimony to his merit. Even Philip of Macedon found it impossible to corrupt him. So abstemious was he with respect to food, that his provision was frequently spoiled before it was consumed. His chastity was invincible. Phryne, a celebrated Athenian courtezan, attempted without success to seduce him. Of his humanity the following pathetic incident is a sufficient proof. A sparrow, which was pursued by a hawk, flew into his bosom; he afforded it protection till its enemy was out of sight, and then let it go, saying that he would never betray a suppliant. He was fond of retirement, and was seldom seen in the city. He was discreet in the use of his time, and carefully allotted a certain portion of each day to its proper business. One of these he employed in silent meditation. He was an admirer of the mathematical sciences; and was so fully convinced of their utility, that when a young man, who was unacquainted with geometry and astronomy, desired admission into the academy, he refused his request, saying that he was not yet possessed of the handles of philosophy. In fine, Xenocrates was eminent both for the purity of his morals and for his acquaintance with science, and supported the credit of the Platonic school by his lectures, his writings, and his conduct. He lived to the first year of the 116th Olympiad, or the eighty-second of his age, when he lost his life by accidentally falling, in the dark, into a reservoir of water.

XENOPHANES, the founder of the Eleaic sect of philosophy among the Greeks, was born at Colophon, probably about the sixty-fifth Olympiad. From some cause or other he left his country early, and took refuge in Sicily, where he supported himself by reciting, in the court of Hiero, elegiac and iambic verses, which he had written in reprehension of the theogonies of Hesiod and Homer. From Sicily he passed over into Magna Græcia, where he took up the profession of philosophy, and became a celebrated preceptor in the Pythagorean school. Indulging, however, a greater freedom of thought than was usual among the disciples of Pythagoras, he ventured to introduce new opinions of his own, and in many particulars to oppose the doctrines of Epimenides, Thales, and Pythagoras. Xenophanes possessed the Pythagorean chair of philosophy about seventy years, and lived to the extreme age of 100 years, that is, according to Eusebius, till the eighty-first Olympiad. The doctrine of Xenophanes concerning nature is so imperfectly preserved, and obscurely expressed, that it is no wonder that it has been differently represented by different writers. Perhaps the truth is, that he held the universe to be one in nature and substance, but distinguished in his conception between the matter of which all things consist, and that latent divine force which, though not a distinct substance, but an attribute, is necessarily inherent in the universe, and is the cause of all its perfection.

XENOPHON, an illustrious philosopher, commander, and historian, was the son of Gryllus, an Athenian, and is supposed to have been born in the fourth year of the eighty-third Olympiad, 445 B. C. When he was a youth, Socrates, struck with his personal appearance, determined to admit him into the number of his pupils. Meeting him by accident in a narrow passage, the philosopher put his staff across the path, and stopping him, asked where those things were to be purchased which are necessary to human life? Xenophon appearing at a loss for a reply to this unexpected salutation, Socrates proceeded to ask him where honest and good men were to be found? Xenophon still hesitating, Socrates said to him, "Follow me, and learn." From that time Xenophon became a disciple of Socrates, and made a rapid progress in that moral wisdom for which his master was so eminent. Xenophon accompanied Socrates in the Peloponnesian war, and fought courageously in defence of his country. He afterwards entered into the army of Cyrus as a volunteer in his expedition against his brother. This enterprise proving unfortunate, Xenophon, after the death of Cyrus, advised his fellow-soldiers to attempt a retreat into Greece. They listened to his advice; and having had many proofs of his wisdom as well as courage, they gave him the command of the army, after the death of their generals. In this command he acquired great glory by the prudence and firmness with which he conducted them back, through the midst of innumerable dangers, into their own country. The particulars of this memorable service are related by Xenophon himself in his Anabasis, frequently called the Retreat of the ten Thousand. After his return into Greece, he joined Agesilaus, king of Sparta, and fought with him against the Thebans in the celebrated battle of Chæronea. The Athenians, displeased at this alliance, brought a public accusation against him for his former conduct in engaging in the service of Cyrus, and condemned him to exile. The Spartans upon this took Xenophon, as an injured man, under their protection, and provided him a comfortable retreat at Scillus. Here, with his wife and two children, he remained several years, and passed his time in the society of his friends, and in writing those historical works which have rendered his name immortal. A war at length arose between the Spartans and Eleans; and Xenophon was obliged to retire to Lepreum, where his sons had taken refuge. He afterwards removed, with his whole family, to Corinth, where he is supposed to have died, about the age of ninety; but the chronology of his life is involved in obscurities from which it cannot easily be extricated.

Of the works of Xenophon there are many editions. The *editio princeps* was printed by Junta, Florent. 1516, fol. An edition more correct, and containing some works omitted in the first, issued from the press of Aldus, Venet. 1525, fol. After several intervening impressions appeared that of H. Stephanus, 1561, fol. Another important edition, several times reprinted, was that of Leunclavius, Basil. 1569, fol. After a long interval, this was followed by the edition of Wells, Oxon. 1703, 5 tom. 8vo. The editor, who is not commended for his fidelity, has added Dodwell's *Chronologia Xenophontea*. This edition of Dr Wells was republished with considerable improvements by Thieme, Lipsiæ, 1763–4, 4 tom. 8vo. A valuable edition with a commentary was afterwards published by Weiske, Lips. 1798–1804, 6 tom. 8vo. We shall only mention another edition, that of J. G. Schneider, Lips. 1815, 6 tom. 8vo. A very useful accompaniment of any edition must not be overlooked, namely Sturz's *Lexicon Xenophonteum*. Lips. 1801–4, 4 tom. 8vo. The materials had partly been collected by Thieme. Of several works of Xenophon there are many separate editions, some of them very elaborate. Several of them have likewise been translated into many different languages. Gail published "Œuvres complètes de Xénophon, traduites en Français, accompagnées du texte, de la version Latine, et de notes critiques." Paris, 1797–1804, 6 tom. 4to. A supplementary volume, in three parts, containing various appendages, was subsequently published. The French version is not entirely new. The translations of the Cyropædia, Anabasis, and Memorabilia, by Dacier, Larcher, and Levêque, have been adopted with some slight modifications. Some of his works have been repeatedly translated into English; but we shall only specify the version of the Cyropædia by the Hon. Maurice Ashley Cooper, of the Anabasis by Edward Spelman, of the Memorabilia by Sarah Fielding, of the Symposium by Dr Wellwood, and of the History by Dr Smith, dean of Chester.

XENOPHON, a native of Ephesus, is supposed to have written towards the close of the second century. His romance, "De Anthia et Habrocome Ephesiacorum libri v." was first edited by Cocchi, Lond. 1726, 4to. An Italian translation had previously been published by Salvini, Lond. 1723, 8vo. The original work appears in the collection of Mitscherlich, *Scriptores Erotici Græci.* Biponti, 1792-4, 3 tom. 8vo. It was about the same time edited by Polyzoes, Viennæ Aust. 1793, 8vo. A much better edition was soon afterwards published by Baron Locella, Vien. Aust. 1796, 4to. Another edition, regarded as the best, was published by Peerlkamp, Harlemi, 1818, 4to. This romance of Xenophon the Ephesian has repeatedly been translated into French and German, as well as Italian; and an English version was published by Rooke, Lond. 1727, 8vo.

XERES DE LA FRONTERA, so called to distinguish it from a small town of the same name near Antequera. It is the capital of a district of the province of Andalusia, in Spain, about ten miles from the sea-shore at Puerto Santa Maria. The early history of this place is obscure, and the origin of its name a very disputable matter with Spanish antiquaries. It was known to the Romans as Acta Regia in the time of Pliny, but only the name is given. It is chiefly remarkable in history as the place where the great battle between the Moors and the Goths was fought in 714, by which, after a contest of eight days, the former were conquerors of the whole of the peninsula. The river Guadalete, on whose banks the decisive action took place, is a small stream, about a mile and a half from the city, which at some seasons of the year is nearly dry. It has a stone bridge, about four miles below which are a wharf and storehouses, from which wine and other goods are shipped for Port St Mary's.

Xeres is situated in the lap of two rounded hillocks, which shelter it to the east and the west; and it covers a considerable extent of ground. The city, properly so called, is embraced by an old crenated Moorish wall, which, though enclosing a labyrinth of narrow, ill-built, and worse drained streets, is of no great circuit, and is so intermixed with the suburbs as to be visible only here and there. The limits of the old town are however well defined by the numerous antique gateways. Some of the buildings are of a unique kind of architecture. It once had ten churches, eleven chapels, four hospitals, twenty-one monasteries and convents. It is doubtful how many of these institutions yet survive the convulsions to which Spain has been subjected for the last quarter of a century. The population is dense, being estimated at 50,000 souls; but the amount is subject to great variations, dependent on the recent or remote occurrence of the last endemic fever generated in its pestiferous gutters and its uncleanly streets and lanes.

The environs of this city afford abundant supplies of corn, especially wheat, of oil, and of cattle. It was long celebrated for its breed of horses, reared by a well-endowed convent of Carthusian monks, now robbed and nearly deserted; but the chief produce is the white wine so generally known by the name of Sherry. This wine is collected by the merchants of the city from the neighbouring vineyards, but some of them are also wine-growers. The quantity annually produced is about 30,000 butts, of 120 gallons each. Of these, rather more than two thirds are sent to England. The remainder is consumed at home, or sent to the United States of America, to the Havannah, to Mexico, or Buenos Ayres. There are not less than twenty-five great mercantile houses, chiefly engaged in the trade with England. There is always on hand a large stock of old wines, which are mixed with the new in such a proportion as is suitable for the various markets. The storehouses are above ground, are vast piles of building, having lofty roofs supported on arches, and their walls are pierced with numerous windows, and thus admit a free circulation of air. Some of these storehouses are so large as to be capable of containing 4000 butts. The oldest wines are kept in huge casks, little inferior to the celebrated tun of Heidelberg, and some of them have wine nominally 120 years old; but the quantity withdrawn is every year supplied from casks of a later growth; and when wine is mixed for shipping, a small portion of the oldest is mingled with the new. Much brandy is mixed with all the wine for exportation, and the merchants are commonly the distillers.

XICOCO, or Sikokf, an island, the smallest of the three that compose the empire of Japan. In length it is 100 miles, and sixty in breadth. It is only separated by narrow straits from the island of Niphon on the one side, and Ximo on the other. This island is almost entirely unknown to Europeans, as they are rigorously prohibited from all intercourse with the Japanese empire.

XIMENA, a city of Spain, in the province of Andalusia, about twenty-five miles from the British fortress of Gibraltar. It is utterly inaccessible for any kind of wheel-carriages. It was once a place of importance, as it gave the title of king to Abou Melic, the son of the emperor of Fez. In more ancient times, it was a Roman station, as is proved by the walls of the castle, and by numerous inscriptions which have been found in its vicinity. The town lies under the shelter of a rocky ledge, which is detached from the mass of the lofty mountains, and is crowned with the ruined towers of an ancient castle, which forms a picturesque view from the surrounding country. Ximena is nearly a mile in length, and principally consists of two long narrow streets, one extending from north to south, and the other leading up to the castle: the alleys between them are in steps up the steep side of the impending hill, and can only be reached on foot. The old castle, of Roman foundation, but of Moorish superstructure, is accessible only on the side of the town, and in former days must have been impregnable. This citadel is 400 yards in length, and varies in breadth from fifty to eighty yards. It is surrounded by a turreted wall, except where the scarped rock has rendered it unnecessary. It has been provided with vaulted tanks and magazines, but from neglect they are in a dilapidated state. It was exposed to great injury in 1811, when it was partially blown up by General Ballasteros, who abandoned it on the approach of the French, to seek a more sure protection under the guns of Gibraltar. The town at the present day is poor, containing about 8000 inhabitants, who are chiefly occupied in agriculture; but many are employed in the seductive but hazardous trade of smuggling tobacco and other goods from Gibraltar into the interior of Spain. The river Sogarganta runs at the foot of the place, and has on its left bank the ruins of a vast building, erected sixty years ago for the purpose of casting cannon-balls for the siege of the British fortress.

Ximenes de Cisneros.

XIMENES DE CISNEROS, Francisco, a celebrated cardinal, was born at Torrelaguna, in Old Castille, in 1437, and studied at Alcala and Salamanca. He then went to Rome; and being robbed on the road, brought nothing back but a bull for obtaining the first vacant prebend; but the archbishop of Toledo refused to grant it, and threw him into prison. Being at length restored to liberty, he obtained a benefice in the diocese of Siguença, where Cardinal Gonzales de Mendoza, who was the bishop, made him his grand vicar. Ximenes some time after entered among the Franciscans of Toledo; but being there troubled with visits, he retired to a solitude named Castanel, and applied himself to the study of divinity and the oriental tongues. At his return to Toledo, Queen Isabella of Castille chose him for her confessor, and in 1495 nominated him archbishop of Toledo, which, next to the papacy, is the richest dignity in the church of Rome. "This honour," says Dr Robertson, "he declined with a firmness which nothing but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. Though obliged to display in public that magnificence which became his station, he himself retained his monastic severity. Under his pontifical robes he constantly wore the coarse frock of St Francis, the rents of which he used to patch with his own hands. He at no time used linen, but was commonly clad in haircloth. He slept always in his habit, most frequently on the floor or on boards, and rarely in a bed. He did not taste any of the delicacies which appeared at his table, but satisfied himself with that simple diet which the rule of his order prescribed. Notwithstanding these peculiarities, so opposite to the manner of the world, he possessed a thorough knowledge of its affairs, and discovered talents for business which rendered the fame of his wisdom equal to that of his sanctity."

His first care was to provide for the necessities of the poor; to visit the churches and hospitals; to purge his diocese of usurers and places of debauchery; to degrade corrupt judges, and place in their room persons whom he knew to be distinguished by their probity and disinterestedness. He erected a famous university at Alcala; and in 1499 founded the College of St Ildephonso. Three years afterwards he undertook the Polyglott Bible; and in order to carry on this great work, invited many learned men to Toledo, purchased seven copies of the Old Testament in Hebrew for 4000 crowns, and gave a great price for Latin

Ximenes.

and Greek manuscripts. *Biblia Sacra Polyglotta,* &c. Compluti, 1514–7, 6 tom. fol. The edition was begun in 1502, and although completed in 1517, was not published till 1522; the court of Rome having during that interval remained in suspense whether it ought not to be entirely suppressed. The cardinal himself was but a doubtful friend of sacred literature; for when it was proposed to translate the Bible into Spanish, in order to convert the Saracens, he opposed it on the ground that men might become Christians without reading the Bible. The Complutensian or Alcala Polyglott contains in the first four volumes the Hebrew, Greek, and Vulgate texts of the Old Testament in parallel columns; and the Chaldee paraphrase at the bottom of the page, with a Latin translation. The fifth volume contains the Greek text of the New Testament, with the Vulgate version. The last contains a Hebrew and Chaldee vocabulary, a Hebrew grammar, and a Greek dictionary. In this Polyglott appeared the first edition of the New Testament in Greek.

In 1507, Pope Julius II. gave Ximenes a cardinal's hat, and King Ferdinand the Catholic intrusted him with the administration of affairs. He was from this moment the soul of every thing that passed in Spain. He distinguished himself at the beginning of his ministry by discharging the people from the burdensome tax called *acavale,* which had been continued on account of the war against Granada; and laboured with such zeal and success in the conversion of the Mahommedans, that he made 3000 converts, among whom was a prince of the blood of the kings of Granada. In 1509 Cardinal Ximenes extended the dominions of Ferdinand, by taking the city of Oran, in the kingdom of Algiers. He undertook this conquest at his own expense, and marched in person at the head of the Spanish army, clothed in his pontifical ornaments, and accompanied by a great number of ecclesiastics and monks. Some time after, foreseeing an extraordinary scarcity, he erected public granaries at Toledo, Alcala, and Torrelaguna, and had them filled with corn at his own expense; which gained the people's hearts to such a degree, that to preserve the memory of this noble action they had an eulogium upon it cut on marble, in the hall of the senate-house at Toledo, and in the market-place. King Ferdinand dying in 1516, left Cardinal Ximenes regent of his dominions; and the archduke Charles, who was afterwards the emperor Charles V., confirmed that nomination. The cardinal immediately made a reform of the officers of the supreme council and of the court, and put a stop to the oppression of the grandees. He vindicated the rights of the people against the nobility; and as by the feudal constitution the military power was lodged in the hands of the nobles, and men of inferior condition were called into the field only as their vassals, a king with scanty revenues depended on them in all his operations. From this state Ximenes resolved to deliver the crown, and issued a proclamation, commanding every city in Castille to inrol a certain number of its burgesses, and teach them military discipline; he himself engaging to provide officers to command them at the public expense. This was vigorously opposed by the nobles; but by his intrepidity and superior address he carried his point. He then endeavoured to diminish the possessions of the nobility, by reclaiming all the crown-lands, and putting a stop to the pensions granted by the late King Ferdinand. This addition made to the revenues enabled him to discharge all the debts of Ferdinand, and to establish magazines of warlike stores. The nobles, alarmed at these repeated attacks, uttered loud complaints; but before they proceeded to extremities, appointed some grandees of the first rank to examine the powers in consequence of which he exercised acts of such high authority. Ximenes received them with cold civility; produced the testament of Ferdinand, by which he was appointed regent, together with the ratification of that deed by Charles. To both these they objected; and he endeavoured to establish their validity. As the conversation grew warm, he led them insensibly to a balcony, from which they had a view of a large body of troops under arms, and of a formidable train of artillery. "Behold," says he, pointing to these, and raising his voice, "the powers which I have received from his Catholic majesty: with these I govern Castille; and with these I will govern it, till the king, your master and mine, takes possession of his kingdom." A declaration so bold and haughty silenced them, and astonished their associates. They saw that he was prepared for his defence, and laid aside all thoughts of a general confederacy against his administration. At length, from the repeated entreaties of Ximenes, and the impatient murmurs of the Spanish ministry, Charles V. embarked and landed in Spain, accompanied by his favourites. Ximenes was advancing to the coast to meet him, but at Bos Equillos was seized with a violent disorder, which his followers considered as the effects of poison. This accident obliging Ximenes to stop, he wrote to the king, and with his usual boldness advised him to dismiss all the strangers in his train, whose number and credit already gave offence to the Spaniards; and earnestly desired to have an interview with him, that he might inform him of the state of the nation, and the temper of his subjects. To prevent this, not only the Flemings, but the Spanish grandees, employed all their address to keep Charles at a distance from Aranda, the place to which the cardinal had removed. His advice was now slighted and despised. Ximenes, conscious of his own integrity and merit, expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and a more extensive authority than the most illustrious of his ancestors had ever possessed; and lamented the fate of his country, about to be ruined by the rapaciousness and insolence of foreign favourites. While his mind was agitated by these passions, he received a letter from the king, in which, after a few cold and formal expressions of regard, he was allowed to retire to his diocese; and he expired a few hours after reading it, on the 8th of November 1517, and in the 81st year of his age.

Ximo
Xulla Islands.

XIMO, or Kiusiu, an island of Japan, second in magnitude to Niphon, being upwards of 200 miles in length, about 150 in breadth, and containing many excellent harbours and flourishing cities. Europeans are rigorously excluded from all intercourse with this island, with the exception of the Dutch, who are still allowed to send their annual vessel to Nangasaki. Near the coast is the city of Firando, where the Portuguese at one time had an establishment, but from which they are now entirely banished. In other respects, Ximo is very little known to Europeans.

XIXONA, a city of Spain, the capital of the fertile partido of that name, in the province of Valencia. It is to the north-east of the port of Alicant, from which its chief productions are exported. The vicinity is covered with abundant woods of palm-trees; and mixed with them are extensive plantations of almonds, which form the greatest article in its commerce. From almonds mixed with honey a conserve is made, which is very delicious, and much in demand in almost every part of Spain. The grapes are abundant, and much brandy is distilled from them. The population of the city is stated to be 5000 souls.

XULLA Islands, four islands in the Eastern Seas. The most considerable of them is Xulla Bessey, which is about eleven leagues in length, in good cultivation, and well inhabited. This island abounds with wax and honey. There is a village adjacent to the south-east point, where the Dutch have a fort, and where ships may procure refreshments. These islands are situated to the south-east of the Molucca passage. They are occasionally invaded by the

Papuas from New Guinea, though the distance is nearly 300 miles. A settlement was formed by the English on one of these islands; but they were induced to abandon it, from the badness of the soil, and other circumstances, and to remove to the coast of Borneo.

XULLABELLA, an island in the Eastern Seas, about twenty-five miles long and six broad. Long. 126. 12. E. Lat. 2. 15. S.

XULLAMANGOLA, an island in the Eastern Seas, about thirty miles long and ten broad. Long. 125. 42. E. Lat. 1. 54. S.

XUN, a city of China, of the second rank, in the province of Sechuen. Long. 103. 20. E. Lat. 30. 18. N.

XYNOECIA, an anniversary feast observed by the Athenians in honour of Minerva, upon the sixteenth of Hecatombæon, to commemorate their leaving, by the persuasion of Theseus, their country seats, in which they lay dispersed here and there in Attica, and uniting together in one body.

XYSTARCHA, the master or director of the xystus. In the Greek gymnasium, the xystarcha was the second officer, and the gymnasiarcha the first. The former was his lieutenant, and presided over the xysti, and all exercises of the athletæ therein.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletæ practised wrestling and running. The gladiators who practised in it were called *xystici*. Among the Romans, the xystus was only an alley, or double row of trees, meeting like an arbour, and forming a shade to walk under.

Y.

Y or y, the twenty-fourth letter of our alphabet. Its sound is formed by expressing the breath with a sudden expansion of the lips from that configuration by which we express the vowel *u*. At the beginning of words, it is commonly taken for a consonant, being placed before all vowels, as in *yard*, *yield*, *young*, &c. but before no consonant. At the end of words it is a vowel, and is substituted for the sound of *i*, as in *try*, *descry*, &c. In the middle of words it is not used so frequently as *i*, unless in words derived from the Greek, as in *chyle*, *empyreal*, &c. though it is admitted into the middle of some pure English words, as in *dying*, *flying*, &c. The Romans had no capital of this letter, but used the small one in the middle and last syllables of words, as in *coryambus*, *onyx*, *martyr*. Y is also a numeral, signifying 150, or, according to Baronius, 159; and with a dash over it, as Ȳ, it signified 150,000.

YA, a city of China, of the second rank, in Sechuen. Long. 102. 39. E. Lat. 30. 9. N.

YABARKULSKAIA, a village of Tobolsk, in Asiatic Russia, on the Irtysch, 120 miles east of Tobolsk.

YACHT, a vessel rigged as a queen's cutter, having a boom-mainsail, foresail, and jib. They are generally used as pleasure-boats.

YADI, a river of Asiatic Russia, which falls into the Obskaia Gulf. Long. 72. 38. E. Lat. 67. 25. N.

YAKOUTSK, one of the four districts into which the province of Irkoutsk, in Asiatic Russia, is divided. It extends as far as the Frozen Ocean, north from the boundary of the provinces of Irkoutsk proper and of Nertschinsk. It is bounded on the east by the province of Okhotsk, which intervenes between the eastern extremity of Asia. It is watered by the great river Lena, which traverses its whole extent from south to north. The climate is so severe as to prevent the ripening of grain to advantage; and even a crop of rye is extremely uncertain, as in June the ground in the vicinity of Yakoutsk is frozen three feet deep. The inhabitants subsist chiefly by hunting; but this formerly lucrative branch of trade has considerably fallen off, in consequence of the depredations made on the game by the activity of the hunters. The sables have become extremely scarce; but other animals still abound, and bring considerable gain.

The tribe that inhabits this dreary region bears the name of the Yacoutes. They formerly occupied the countries on the Angara and Upper Lena, and are supposed to have been originally a Tartar race; but being driven from their original abodes by the Mongols and Burats, they have taken shelter in the frozen solitudes of the Lower Lena. They occupy an extensive territory, extending eighteen degrees from north to south, and nearly fifty from east to west. This desolate country is but thinly peopled. The number of males paying tribute amounts to 34,979, which, it is supposed, may be about the third of the entire number of both sexes. Those who inhabit the southern districts of this province are tolerably rich and industrious, and possess the usual size, activity, and vigour: but those farther to the north live poorly; they are seldom able to procure bread, and feed on onions, garlic, and other roots, with various sorts of berries, both fresh and preserved, which form their chief luxuries. They are remarkably ignorant and superstitious, and live in the continual dread of evil spirits. The Shamans, a set of magical impostors, enjoy unbounded influence among them. They are eager for spirits, and greedily drink brandy when they can procure it, and use as a substitute fermented mare's milk, which forms the chief luxury of their feasts. They now submit quietly to the Russian yoke, though they long continued to view that nation with hostility. They acknowledge their subjection by an annual tribute, generally paid in furs.

Yakoutsk, the capital of the above province, is situated on the western bank of the Lena, on a plain surrounded by mountains, which enclose it at the distance of ten or twelve miles. It is a place of some trade, notwithstanding the inhospitable climate in which it is situated, being the emporium of the fur trade; all the furs which are collected in the extensive regions of the north being brought to this place, as are also all the Russian and Asiatic commodities which are imported in exchange. It also forms a species of entrepôt for the Russian trade with Kamtschatka and the western coast of America. The dreary winter is the greatest disadvantage of this place. The cold is excessive; and the inhabitants are almost entirely confined to their houses, the daylight continuing during the deadness of the season for only a few hours. They consume their time, accordingly, between drinking and sleeping; and they use ice as the most effectual mode of stopping up every chink and crevice, being applied, like double glass, to the outside of the windows. Yakoutsk contains 500 or 600 houses, and about 3000 inhabitants, who for the most part are Cossacks or Yakoutes. Long. 140. 8. E. Lat. 60. 2. N.

YAMSKOI, a fortress of Asiatic Russia, in the government of Okhotsk, at the mouth of the river Yama, about 800 miles north of Okhotsk.

YAMYCHEFSKAIA, a fortress of Asiatic Russia, in the government of Tomsk and district of Blisk, situated on a high bank of the Irtysch. It was built in 1715 of wood, and was rebuilt in 1765 of earth, with 200 well-built houses attached to it, besides barracks for the garrison, magazines, and a stone church. The inhabitants are exposed to inconvenience from the quantity of sand that is blown from the river when the wind comes from that quarter. Long. 77. 50. E. Lat. 60. 12. N.

YANG, the name of two towns in China, of the third rank, one in Chan-si, near the river Han, the other in Yunan. There is also a town of this name in Corea.

YANG-CHAN, a town of China, of the third rank, in Quang-tong.

YANG-CONG, a river of China, which runs into the Kincha.

YANG-HO, a river of China, which joins the San-cam-ho. Long. 112. 49. E. Lat. 40. 23. N.

YANG-KANG, a town of China, of the third rank, in Tche-kiang, twenty-two miles south-east of Kin-hoa.

YANG-TCHEOU, a city of China, of the first rank, in Kiang-nan, situated on the bank of the Royal Canal, where it crosses the great river Yang-tse-kiang. It is a place of great trade, and, besides dealing in all manner of Chinese goods, is a great mart for salt, which is made on the sea-coast, and which is distributed over the country by means of small canals cut for this purpose, and ending in the great canal. It is 485 miles south-south-east of Peking. Long. 118. 54. E. Lat. 32. 26. N.

YANG-TSE-KIANG, the largest river in the Chinese empire, and one of the greatest in the world. Its source, which is unknown to Europeans, is laid down in the Chinese maps as situated among the mountains of Tibet. It flows during the first part of its course along the borders of China; after which it enters the Chinese territory, and passes, in a westerly course, through Sechuen, Houquang, and Kiang-nan, the central provinces, diffusing, far and wide, commerce and fertility, and facilitating the internal intercourse of the empire. Increased in its progress by numerous tributary streams, it becomes truly magnificent when it passes the great city of Nanking, from the fleets of trading craft with which it is covered; and there is thence a continued succession of cities, towns, and villages, diversified by the high cultivation of the intervening country. It falls into the Gulf of Tsong-ming, in the Eastern Seas, about 120 miles to the east of Nanking.

YANGUIN, Chainwah, a town of the Birman empire, situated on the east bank of the Irrawuddy river. It is the station of a custom-house. Long. 95. 45. E. Lat. 17. 7. N.

YANTCHIN or Wantchin, a city of China, of the second rank, in Quangsee. Long. 106. 51. E. Lat. 28. 1. N.

YAO, a city of China, of the second rank, in Chan-si. Long. 108. 31. E. Lat. 35. 54. N.

YAO-NGAN, a city of China, of the first rank, situated on the frontier province of Yunan. Near it is a well producing a very white salt. Long. 101. E. Lat. 25. 33. N.

YAO-TCHEOU, a city of China, situated on the northern side of the Poyang lake. It is a great emporium of the porcelain manufactures, and supports a great population. Long. 116. 14. E. Lat. 29. 0. N.

YARD *of a* Ship, a long piece of timber suspended upon the masts, to extend the sails to the wind. All yards are either square or lateen; the former of which are suspended across the masts at right angles, and the latter obliquely. The square yards are nearly of a cylindrical surface. They taper from the middle, which is called the *slings*, towards the extremities, which are termed the *yard-arms*; and the distance between the slings and the yard-arms on each side is by the artificers divided into quarters, which are distinguished into the first, second, third quarters, and yard-arms. The middle quarters are formed into eight squares, and each of the end parts is figured like the frustum of a cone. All the yards of a ship are square except that of the mizen.

Yards also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. See Docks.

YARE, among sailors, implies ready or quick: as, be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is sometimes also used for bright by seamen: as, to keep his arms yare; that is, to keep them clean and bright.

Yare, a river of Norfolk, which runs from west to east through that county, passing by Norwich, and falling into the German Ocean at Yarmouth.

YARKUND, a city of Cashgar, in that part of Chinese Tartary which commonly goes by the name of Little Bucharia. It is situated on a river of the same name, on the eastern side of that great range of mountains which extends northwards from the Himalaya range, and divides Chinese from Independent Tartary. This city, after enjoying a high degree of celebrity in that part of Asia, was destroyed by Meerza Abubekr, grandson of Timour, who however restored it to prosperity, when its population increased; and the air being salubrious, he made it his residence, adorning it with splendid edifices, bringing water into the streets, and in other ways rendering it fit for a royal abode. Its walls are about 1200 feet high; and numerous gardens, the finest in the world, were planted around it. It is at present defended by a wall of stone cemented with mud, in which there are five gates. The houses are mean, being built of stone and mud, and have all balconies. The bazaar runs from east to west, and is described as consisting of a range of seats upon a platform, behind which there are handsome shops, chiefly occupied by Chinese. It contains more than ten large colleges, for the support of which lands are assigned, and plenty of caravanserais for the accommodation of travellers. The town is watered by canals from the river, from which are filled certain reservoirs, of mud and stone, which supply the inhabitants with water when the canals are frozen and the river low. The water of the river is also employed in irrigating the surrounding cultivation and gardens. The inhabitants of this and the other towns in this part of Asia are chiefly mechanics, merchants, and teachers or priests. Many of them are afflicted with the glandular swelling in the throat called goitre. The women of the country, whether high or low, do not wear veils. The Russians carry on a commercial intercourse with Yarkund, which is a great emporium of inland trade. It is within the dominion of the Chinese, under whose government it has been for the last eighty years. Long. 78. 27. 45. E. Lat. 38. 19. N.

YARM, or Yarum, a market-town of the north riding of Yorkshire, in the wapentake of Langbarough, 244 miles from London. It stands on the river Tees, over which is a handsome bridge, and consists of one long wide street. It has a considerable trade by sea, and much corn and lead are shipped for London. There were in ancient times two monasteries, founded by the family of Bruce. It has a good market on Thursday. The population amounted in 1821 to 1504, and in 1831 to 1636.

YARMOUTH, a seaport town and borough of the county of Norfolk and hundred of East Flegg, 124 miles from London. The old town is situated on the eastern bank of the Yare, and is connected with the new town, called Little Yarmouth, by means of a bridge over that river. The old town, which is still surrounded by walls, consists of four principal lines of streets running nearly parallel with the river, and of about 150 narrow lanes called rows, which are impassable for wheel-carriages. The principal streets are well built and wide, opening in some places to the spacious quay, market-places, and squares. The best dwelling-houses are situated along the quay, which is considered the finest in the kingdom, having in the centre a noble promenade, planted on each side with trees, and reembling those on the banks of the Seine at Paris. The art of the town beyond the walls consists of extensive arehouse premises, and inferior dwelling-houses. The ew town principally consists of substantial private resi ences; and the space between them and the river is oc upied by docks, timber-wharfs, building-yards, and other remises connected with the trade of the port. The reets are well lighted with gas, and well supplied with ater. The town-hall, church, and theatre, are hand ome buildings. In addition to the church, there are other wo chapels connected with the establishment, and places worship for the various bodies of dissenters. There is an xtensive manufactory for crapes and other silk goods, which said to be in a thriving condition, and which gives em loyment to about 500 persons, principally women. Ship uilding, and the various trades connected with it, are also arried on to some extent in Yarmouth; nevertheless it annot be considered as a manufacturing town, but derives s importance and prosperity from the trade and commerce hich it owes to its situation and port. The rivers Yare, Vav ey, and Bure, which unite in Braydon Water, con guous to the town, are navigable; the first to Norwich, he second to Bungay, and the third to Aylsham; and se ures Yarmouth an extensive inland trade in the expor ation of the agricultural produce of the districts that are aversed by these rivers, and in supplying them with coals nd other heavy goods. The exportation of grain and malt om this port is considerable; but the principal business of armouth is the herring and mackarel fisheries, and the uring and exportation of this staple commodity to foreign ountries, particularly to the states bordering the Mediter anean. An extensive timber trade with the Baltic is also arried on; and there are at present nearly 400 square gged vessels belonging to the port. Yarmouth Roads have ong been the principal rendezvous for the collier trade; nd the town derives some advantages from the supply of resh provisions to the numerous shipping employed in this rade. The harbour of Yarmouth, formed by the river are, has an awkward entrance, which, as is always the ase in harbours of this description, is obstructed by a ar. Great attention, however, is bestowed on the reme ying of these defects, and on the general improvement of he port. Vessels drawing about twelve feet of water, or f about 200 tons burden, can cross the bar, and proceed o the town at spring-tides. Yarmouth has two weekly markets, and that held on Saturday is much frequented. An annual fair is held on the Friday after Good Friday, ut is neither of importance to the town nor its neighbour ood. The town is divided into six wards, and is govern ed by a mayor, twelve aldermen, and thirty-five council ors. It returns two members to the House of Commons. The duties collected here in 1837 amounted to L.66,169, and in 1838 to L.70,775. The population amounted in 821 to 18,040, and in 1831 to 21,448.

Y RMOUTH, a small market-town of the Isle of Wight nd the county of Hants, a part of the parish of Medina, 100 miles from London. It stands on a rising ground facing he sea, and retains traces of having been much larger at ome former period than it is at present. In its present tate it consists of several well-built streets. There is but ittle trade carried on. The population amounted in 1821 o 5, and in 1831 to 586.

Y RMUC, or YARUN, a village of Palestine, in the dis rict f Saphet, on a small river of the same name, which alls nto the lake of Tiberias. It is twenty-four miles south f S het.

Y RMUC, a river of Syria, the ancient Marsyas, which uns nto the Orontes near Apamea.

Y ULY, a town of Hindustan, province of Berar, nine een miles south-west from Nagpoor. Long. 79. 1. E. Lat. 26. . N.

YAWNING, an involuntary opening of the mouth, generally produced by weariness or an inclination to sleep. Yawning, according to Boerhaave, is performed by expanding at one and the same time all the muscles capable of spontaneous motion, by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air, and gradually and slowly breathing it out after it has been retained for some time and rarefied, and then restoring the muscles to their natural state. Hence the effect of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and consequently to qualify the muscles and organs of sensation for their various functions. Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching the limbs. To these a person is most inclined just after sleep, because a greater quantity going off by the pores of the skin than at other times, whenever a person wakes, the increasing contraction that then happens closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contact of their fibres, and the enclosed matter, by degrees throw it off. Hence we see the reason why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations. The advantages of some little exercise just after waking in a morning are considerable, as it throws off all the perspirable matter that is ready for its exit from the body. When yawning is troublesome, Hippocrates says that it is cured by long, deep respiration, or drawing in the air at long intervals.

YAYNANGHEOM, a town of the Birman empire, situated on the eastern bank of the Irrawuddy river. It carries on a very considerable traffic, and has a manufacture of earthen ware. Five miles east of the town are situated the petroleum wells, which supply the whole kingdom with this oil, which is used in lamps and for all other purposes of train or wood oil, and is sold very cheap. The government farms out the ground that supplies this extraordinary oil, and the renter draws it out at his own expense. The depth of the pits is about thirty-seven fathoms, and it is drawn out by means of pots, which are let down to the bottom by ropes. Long. 94. 35. E. Lat. 20. 28. N.

YEAR, in *Astronomy* and *Chronology*. See ASTRONOMY and CALENDAR.

YEAST, or YEST, a head or scum rising upon beer or ale while working or fermenting in the vat. See BREWING.

YELCUNDEL, a district of Hindustan, province of Hyderabad, situated between the eighteenth and nineteenth degrees of north latitude, and bounded on the north by the river Godavery.

YELL, one of the islands of Shetland, lying north-east from the Mainland, and divided from it by an arm of the sea, called Yell Sound. By some it is thought to have been the Thule of the ancients. It is seventeen miles long and from six to eight broad. It is very mountainous, and full of moss; but there are considerable pastures, in which the islanders feed a great many sheep; and it also affords plenty of peat. It has eight large harbours. It is divided into two parishes; and its inhabitants are partly supported by the cod, ling, and whale fisheries, and by agriculture. Their number in 1831 amounted to 3492.

YELLOW, one of the original colours of light.

YELLOW RIVER, or HOANGHO, a great river of China, which, along with the parallel stream of Yang-tse-kiang, or Blue River, has its sources in the unknown clefts of the Tibetian Mountains, probably the lofty central chain of the Asiatic continent; and after a tortuous course of

Yellow Sea || Yemen.

great length, estimated at about 1800 or 2000 miles, it falls into the Yellow Sea by numerous channels, in about 33° north latitude. In the early part of its course it runs northward, and is carried beyond the limits of the Chinese empire, being turned aside by a lofty chain of mountains for 500 or 600 miles. It afterwards turns into an opposite direction, and reaching the original line of its course, again enters the Chinese empire, and by its winding progress diffuses more widely the benefit of its waters. Though broad and rapid, it is in many places so shallow as to be unfavourable for navigation. It is also liable to overflow its banks, so that it has been necessary to raise dikes for the defence of the surrounding country.

Yellow Sea, a large gulf, about 120 miles in length and eighty in breadth, connected with the Gulf of Pe-tche-lee, and extending along the coast of the province of the same name in Chinese Tartary.

YELPOORA, a small town of Northern India, province of Canara, situated above the Ghaut Mountains, in the Soonda district. It is inhabited by Christians, Mahommedans, and Hindus. Long. 74. 55. E. Lat. 14. 57. N.

YEMEN, a large province of Arabia, comprehending its finest and most fertile portion, situated partly on the Red Sea and partly on the Indian Ocean. It is surrounded by the provinces of Hadramaut, Nedjed, and Hedjaz. It was celebrated by the ancients under the title of Arabia Felix, but modern researches do not by any means justify this appellation: some parts are no doubt fertile, but in general it is barren and unproductive. It is divided into two parts, differing greatly in soil and climate. The plain of the Tehama, which forms a broad belt along the whole of the coast, consists almost entirely of a waste of dry and unproductive sand. It is about two days' journey in breadth, and is scorched by torrid heats. The Djebal, or mountainous district, in the interior, presents in many parts a more agreeable aspect. The hills, though precipitous, are fertile in many spots, and enjoy a more temperate air. The lower declivities are covered with trees and aromatic shrubs, and the mountain chains are divided by fine valleys, which, being watered by numerous streams, can be advantageously cultivated. The natives are industrious agriculturists, though their instruments are rude; and in many districts the fields are cultivated like gardens. The grains chiefly raised are barley, millet, and dhourra: there is not an adequate supply of water for the cultivation of rice. The aromatic plants which grow upon the sides of the hills are the most valuable products of this region. The coffee produced in Yemen has always possessed a flavour which cannot be rivalled by that of any other country to which the shrub has been transplanted from this its native region; and Mocha coffee is in request all over the world. The balm of Mecca, and the tree bearing incense, are also produced in Yemen, though they are found in greater perfection on the opposite coast of Africa.

Like the rest of Arabia, Yemen was formerly parcelled out among a number of different sovereigns in unequal portions; but it has been formed into a considerable monarchical state, subject to a sovereign who assumes the modest title of Imam or doctor, but exercises over his subjects an authority nearly absolute. He is forced however to pay respect to the pride of the aristocracy, namely, the schiechs or hereditary chiefs, who here, as over all Arabia, possess a high influence, and, seated in their strong castles in the interior, often set his mandates at defiance. The sovereigns of Yemen were formerly reduced under the Saracen power, and afterwards under the soldans of Egypt. They were since menaced by the growing power of the Wahabees, who made themselves masters of all the seaports except Mocha; but their power and kingdom being extinguished by Mehemet Ali, this country came under his dominion. In consequence of the late successful operations of the British fleet against Syria, it will revert with that country to the rule of the sultan.

YEN, a river of China, which falls into the Hoangho, seventeen miles south-east of Yen-tchang.

YEN-KIANG, a city of China, of the second rank, in Pe-tche-lee. Long. 125. 30. E. Lat. 40. 30. N.

YEN-NGAN, a city of China, of the first rank, in Chan-si, situated in an agreeable plain surrounded by lofty mountains. The territory abounds in fens. Long. 108. 49. E. Lat. 36. 44. N.

YEN-PING, a city of China, of the first rank, in Fokien. It is situated on the river Min-ho. It is not large, but is considered a stirring commercial city. Long. 117. 54. E. Lat. 26. 40. N.

YEN-TCHEOU, a city of China, of the first rank, in Tchekiang, situated on a river near the sea, so that the tide approaches its walls. It contains beautiful buildings. In its vicinity are mines of copper, and trees which yield a varnish that is much esteemed for lackered work. In Shantung there is another city of this name, of the first rank. Its territory is plentifully watered by many streams, being enclosed between the Hoangho and another great river. It has also numerous dependent cities, nearly as large as itself. The territory is celebrated as being the birth-place of Confucius. Long. 116. 36. E. Lat. 35. 44. N.

YEOMAN, the first or highest degree among the plebeians of England, next in order to the gentry. The yeomen are properly freeholders, who having land of their own, live on good husbandry.

Yeoman is also a title of office in the king's household, of a middle place or rank between an officer and a groom.

Yeomen *of the Guard* were anciently 250 men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 yeomen in constant duty, and seventy more not in duty; and as any of the 100 dies, his place is supplied out of the seventy. They are dressed after the manner of King Henry VIII.'s time. They formerly had diet as well as wages when in waiting, but this was withdrawn in the reign of Queen Anne.

YEOVIL, a borough-town of the county of Somerset, in the hundred of Stone, 121 miles from London. It stands on the river Yeo or Ivel, which joins the Parret, and runs to the Bristol Channel. It is a well-built town, and was once famed for its woollen manufactures; but these have been superseded by the making of gloves, which now forms the chief occupation, and has augmented the population. Besides the church, there are various places of worship for dissenters. There is a well-frequented market on Friday. The inhabitants amounted in 1821 to 4655, and in 1831 to 5921.

YEOWAH, a town of the Birman empire, on the west bank of the Irrawuddy river. Long. 94. 30. E. Lat. 20. 55. N.

YERNAGOODUM, a town of Hindustan, province of the Northern Circars, in the vicinity of which are fine forests of timber, which might be conveyed to the sea down the streams of the Wurda and Godavery. Long. 81. 39. E. Lat. 16. 58. N.

YETHOLM, a parish on the confines of England, in the county of Roxburgh, containing two villages of the same name. One of these, Town Yetholm, is the place where the largest colony of Gipsys in Scotland is to be found. The strolling habits and vagabond life which they lead are too well known to require any description here; but it may be stated, that in consequence of the operation of the new police act for Scotland and England, there is every probability of a change taking place in their erratic mode of life, by their being compelled to settle to steady occupations in a fixed place of abode, or otherwise being liable to be imprisoned as vagrants. Their number is at present about 100. The village is situate in a valley about one mile in length and a quarter of a mile in breadth, through which the Bowmont flows. The parish church is situated in Kirk Yetholm, while in Town Yetholm there are two dissenting places of worship. The population of the parish in 1831 was 1289.

YEZD, a city of Persia, in the province of Khorassan, on the frontier of Seistan. It is situated in a sandy desert, contiguous to a range of lofty mountains. Being a great commercial emporium between Hindustan, Bokhara, and Persia, it is a place of considerable trade, is large and flourishing, and the bazaar is supposed to contain 20,000 houses, besides those of the Guebres or worshippers of fire, which are estimated at 4000. These Guebres are a persecuted remnant, who, after the extinction of the greater part of their race, are still suffered to exist in a state of oppression, being subjected to a poll-tax of twenty piastres, besides the various exactions of the Persian government. There were formerly many opulent Hindus in this place; but, in order to escape the exactions of the governor, who intended to plunder them, they all fled in one night to Candahar, where they have established themselves, and since that period there have not been more than nine Hindus in Yezd. The city imports corn from Ispahan. Cattle are scarce, and sell high. The town is famous for the manufacture of silk stuffs which are superior to any in Persia. The fort has but a mean appearance, and the town is destitute of a wall. It is about 300 miles east of Ispahan. Long. 55. 30. E. Lat. 32. 30. N.

YEZDIKHAST, a town of Persia, in the southern part of the province of Irak. It is the first which occurs in the highroad to Ispahan, after passing the frontier of Laristan.

YGUISAN, a small island among the Philippines, near the north coast of Panay. Long. 122. 32. E. Lat. 11. 35. N.

YNCA. See Inca.

YN-YUEI, a city of China, of the second rank, in Yunan. Long. 98. 24. E. Lat. 25. 58. N.

YOKE, in *Agriculture*, a frame of wood fitted over the neck of the oxen, by which they are coupled together, and harnessed to the plough.

Yoke *of Land* is the space which a yoke of oxen, that is, two oxen, may plough in one day.

YONG-NING, a city of China, of the first rank, in Yunan, on the borders of Tibet, situated near a fine lake. The neighbouring country abounds in cows having those long tails with which the great men of China are accustomed to adorn themselves. 1095 miles south-west of Peking. Long. 100. 24. E. Lat. 27. 50. N. Of the same name there are several other cities. of the second and third rank.

YONG-NGAO, a small island near the coast of China, in Quangtong, twenty miles south-south-east of Macao.

YONG-PE, a city of China, of the first rank, in Yunan, in a mountainous district, yet fertile, and watered by a fine lake. Long. 100. 34. E. Lat. 26. 42. N.

YONG-PING, a city of China, of the first rank, in Pe-chelee, on a river which runs into the Gulf of Leao-tong. It is environed by the sea, by rivers, and by mountains covered for the most part with fine trees. From the sea it is supplied with great plenty of all the necessaries of life. Not far from the city stands a fort named Chun-hai, which is the key of the Tartar province of Leao-tong. This fort is near the eastern extremity of the great wall. 115 miles east of Peking. Long. 118. 34. E. Lat. 39. 55. N.

YONG-TCHANG, a city of China, of the first rank, in Yunan. It is large and populous, and is built in the midst of high mountains, in the neighbourhood of a savage people. The country produces gold, honey, wax, amber, and a vast quantity of fine silk. 270 miles south-west of Peking. Long. 99. E. Lat. 25. 6. N.

YONG-TCHEOU, a city of China, of the first rank, in Houquang, forming the most southerly city of the province. It is situated on a fine river, amid verdant and well-cultivated mountains, particularly abounding in bamboos. 882 miles south-west of Peking. Long. 111. 15. E. Lat. 26. 10. N.

YONNE, a department in the north-east of France, formed out of Auxerois in the ancient Burgundy, and Sennois, a part of ancient Champagne. It extends in north latitude from 47° 22′ to 48° 37′, and in east longitude from 2° 47′ to 4° 19′. It is bounded on the north by the departments of Seine-Marne and Aube, on the east by Aube and Côte d'Or, on the south by Nievre, and on the west by Loiret. It is 2846 square miles in extent, is divided into five arrondissements, thirty-seven cantons, and 481 communes, containing 355,237 inhabitants in 1836, all of whom adhere to the Roman Catholic church. The face of the country is undulating, with valleys extending between hills of moderate height. In the western division, the soil chiefly consists of clay, which is much covered with wood, and overrun with wet marshy pools and ditches. In the south and east it is calcareous and stony, and in the north a productive loam. It is on the whole tolerably fertile, yielding more corn than is required for the consumption of the inhabitants. The climate is mild and peculiarly healthy. The chief river, from which the department takes the name, is navigable. It enters from Nievre, flowing from south to north; and after receiving the waters of the Vannes, the Armoncon, the Seray, the Eure, the Voisin, and the Tholon, it passes into the department of the Seine and Marne. The canal of Burgundy terminates near to St Florentin, and the canal of Briare touches a small part of this division of the kingdom.

The chief occupation is agriculture, and the corn grown here is of a good quality, especially in the northern part; but in the east and the south the cultivation of the vine is found a more beneficial pursuit. A large quantity of excellent wine is made, especially in the district adjoining to Côte d'Or. There is nothing remarkable in either their cows or sheep; and the cultivation of green crops is very rarely attended to, the only good pasture being the natural meadows on the banks of the Yonne. Fruit trees are very abundant, and yield large annual crops, especially of plums; and the nuts and chestnuts are objects for export. The other articles exported are wood, charcoal, wine, hay, and live cattle. There are manufactures of cotton, linen, and woollen; paper-mills, tanneries, glass-houses, and potteries; but barely sufficient for the home demand, and all upon a contracted scale. There are some small mines of iron, not yielding more than 300 tons of raw iron, which does not suffice for the supply. This department elects three deputies to the representative chamber.

YON-NIM-KIEN Hotun, a town of Chinese Tartary, on the eastern coast of the Yellow Sea, 263 miles east of Peking.

YOOL or Yowl Islands, a cluster of small islands in the Pacific Ocean, so called by Captain Forest in 1774. They were called, in 1788, Tattee Islands by Mr Meers. They are situated off the north coast of Wagiou, about the 31st degree of E. long., and are surrounded by coral reefs.

YORK, an English county, by far the largest in the kingdom. In extent it more than equals the two next largest counties, viz. Devonshire and Lincoln. According to the parliamentary returns of 1831, the whole surface is 5836 square statute miles, or 3,730,040 acres. or nearly one-ninth part of the southern division of the united kingdom. This county is bounded on the east by the German Ocean; on the north by the counties of Durham and Westmoreland; on the west by the latter county and Lancashire; and on the south by Cheshire, Derbyshire, Nottinghamshire, and Lincolnshire. The river Tees on the north, and the Humber on the south, are boundaries marked by the hand of nature, and so, in some degree, are the ranges of hills on the western sides; but these last are indefinite, and, like most other divisions of counties, those of Yorkshire are mostly imaginary lines, whose position is chiefly ascertained by local tradition.

This county is divided into three portions called Ridings, designated from their positions as the East, the North, and the West, and one smaller division called the Ainsty of York, comprehending the city of that name and a district surrounding it. As the statistical account of the population may be more appropriately shewn under the heads of the respective divisions, we need here only state the collective results of the several decennial enumerations that have been made in the present century. They are as follows. In 1801, 858,892; in 1811, 986,174; in 1821, 1,173,187; and in 1831, 1,371,359.

The members of the upper house of parliament taking their titles from places in the county are the following, viz. dukes of Richmond, Leeds, and Cleveland; marquis of Normanby; earls of Doncaster (duke of Buccleuch in Scotland), of Scarborough, of Pomfret, of Beverley, of Harewood, and of Ripon; Barons Hawke, Bolton, Ribblesdale, Prudhoe, and Wharncliffe. The representatives of Yorkshire in the House of Commons have been much altered by the reform act of 1832. The three ridings return two members each; the boroughs of Aldborough, Boroughbridge, and Hedon, which returned two members each, have been disfranchised; and Thirsk and Northallerton, which returned two, now elect but one each. The large towns of Leeds, Sheffield, Bradford, and Halifax, have been created boroughs, electing two members each, as well as Wakefield, Whitby, and Huddersfield, which have one each. The whole county thus returns five more members than it did before the passing of the act in question.

The wealth and fertility of Yorkshire are much promoted by the rivers which in various directions pass through it, and by the several navigable canals, which either unite the different branches of those rivers, or draw from them a supply of water for their immediate use. The Tees forms a boundary to Yorkshire on the side of Durham, but a very small portion of its waters is collected from the former county. In the west riding, the rivers Ribble and Wenning flow towards the Irish Sea; but they are inconsiderable streams till they enter Lancashire. All the others that have their sources in Yorkshire empty themselves into the German Ocean, in a river then denominated the Ouse, through the great estuary the Humber. The Ouse is composed of two small rivers, the Swale and the Ure, which unite below Boroughbridge, and, soon after receiving the waters of the Nidd, passes by the city of York, to which place it is navigable. It is soon afterwards increased by the reception of the Wharfe on its right bank, and of the Derwent on its left. It then receives the river Aine, whose waters near Snaith have been increased by those of the Calder and its numerous tributary rivulets; and soon after, on the same bank, the river Don, when its breadth is nearly equal to that of the Thames. The most important canal is the Leeds and Liverpool, which connects together, by internal navigation, the two important ports of Hull and Liverpool, and affords to the manufacturers facilities of exporting their productions from either of those places, as may be most suitable for the various markets to which they are destined. There are several shorter canals, which connect the towns with the navigable rivers, or convey from the coal-mines their important produce. Many projects for the construction of railroads through this county have been formed, and some of the works have been begun; others are yet waiting for parliamentary or legal decisions; but a few years will produce great changes in the modes and facilities of communication.

North riding.

The north riding of Yorkshire is divided into ten wapentakes, two liberties, and the towns of Richmond, Scarborough, and Whitby. The area of the riding is 1,315,200 acres, as measured on the best maps; while that resulting from the returns of each parish is only 1,275,820, a discrepancy that cannot be accounted for. Mr Tuke forty years ago estimated the area at 1,311,187 acres, of which 442,565 acres were then uncultivated. It is now supposed, though not ascertained, that more than one half of what was then classed as uncultivated has, within the last forty years, been rendered more or less productive.

The population at the four decennial enumerations has been found to be, in 1801, 158,225; in 1811, 169,391; in 1821, 187,452; and in 1831, 190,756. At the last of these periods, the males were 93,203, and the females 97,553. The families were 40,760, of whom 17,964 were chiefly employed in agriculture, 11,298 in trade or handicraft, and 11,498 were not comprised in either of the preceding classes. The number of males at that time under twenty years of age was 47,396; the occupiers of land employing labourers was 4950, of those not employing labourers 4334; the labourers employed in agriculture were 14,646; the persons employed in manufactures, or in making manufacturing machinery, were 1009; those employed in retail trade or handicraft, as masters or workmen, 12,749; the capitalists, bankers, professional or other educated men, 1870; the labourers employed in labour not agricultural, 4391; other males twenty years of age, excepting servants, 2836; male servants twenty years of age, 615; and under twenty years, 229. The female servants were 9261.

The land on the sea-shore is generally lofty, and the cliffs precipitous, varying in height from one hundred and fifty to nine hundred feet. Within this narrow sea-boundary is a tract called the Eastern Moorlands, about thirty miles from east to west, and fifteen from north to south. It is apparently a barren country, penetrated with some beautiful and fertile valleys, which are indeed narrow; but the hills that rise on both sides of them are cultivated nearly to the top. Rosebury-Topping, a mountain whose summit is 1480 feet above the level of the sea, overlooks the beautiful vale of Cleveland, and the other parts of the western division of this riding, especially the rich and picturesque districts in the vicinity of Boroughbridge and Richmond. The western moorlands are superior in fertility to the eastern. Some of the dales in this district are celebrated for their beauty and fertility, particularly Wensley Dale, Swale Dale, and some of the smaller sheltered spots.

The cultivation varies so much that it is difficult to give even an outline of the different practices. The greater portion of the land is in pasture. In Cleveland and Rye Dale the best wheats are grown; and the average produce is somewhat more than twenty-three bushels to an acre. Barley is not much grown, nor rye, except on poor and sandy soils. Oats are extensively cultivated, and great crops are produced in Rye Dale and some other of the vales. They are chiefly consumed in the manufacturing districts, where they form the food of the greater part of the labourers. In many parts of this riding, a mixture of wheat and rye is sown: this corn is commonly known by the name of meslin, and is made into flour, of which the bread of almost the whole district is composed. The breeding and fattening of cattle, and the operations of the dairy, are of more importance to this riding than the growth of corn. The cows are generally of the short-horned kind, and they are of small size, but clean made, and fine in the bone. The average weight of the oxen, when fat, is about forty stone. The sheep are still mostly of the old large coarse-boned race, but improvements are proceeding by the gradual mixture of the Dishley and Northumberland breeds. The fine wool clipped in this district is mostly consumed in the domestic manufactures of hosiery, in the knitting of which the females are very generally occupied.

The whole of Yorkshire has been long celebrated for its attention to the breeds of horses, but the chief seat for rearing them is in the north riding. The horses of Cleveland being clean made, strong, and active, are well calculated for draft; those of the vale of York, by the introduction of the racing blood, are fitter for the saddle. The vales of the eastern moorlands rear many horses of a smaller but useful breed.

The mineral productions of this division of Yorkshire are not of great account. To the west of Richmond some lead mines are advantageously worked. Iron and copper have been formerly raised. The former metal is still produced near Whitby and Scarborough, but the mines of the latter are abandoned. Coal is found in various parts of the riding, but the quantity is small and the quality bad; and hence the chief supply of fuel is obtained from Durham. The most valuable mineral production is alum, which is collected and prepared in large quantities at different works on the northern shore of the riding.

This division of Yorkshire can scarcely be viewed as a manufacturing district. The greatest portion of those employed in making goods are weavers of linen, which is a kind of domestic industry, in no one place employing more than 120 persons, and the whole of them not exceeding 400. Ship-building, and the attendant operations of making ropes, sail-cloth, and iron-work, employ many hands in and near Whitby; and on that part of the coast, at the proper season, the herring-fishery affords some occupation.

The most striking remains of antiquity in the riding are Scarborough Castle, and the abbeys of Rievaulx, Byland, and Whitby.

Among a vast number of seats of noblemen and gentlemen, some of the most conspicuous and celebrated are, Bishopsthorpe, archbishop of York; Castle Howard, earl of Carlisle; Duncombe Park, Lord Feversham; Hornby Castle, duke of Leeds; Kirkleatham Hall, Sir Charles Turner, Bart.; Marske Hall, Honourable L. Dundas; Mulgrave Castle, the marquis of Normanby; Newby Park, Earl de Grey; Brompton, Sir George Cayley, Bart.; Rokeby, J. B. S. Morritt, Esq.; Gersham, duke of Cleveland; and Aske, earl of Zetland.

The largest towns in the riding, and the population of them in 1831, were these: Scarborough, 8369; Whitby, 7763; Malton, 4173; Richmond, 3900; Northallerton, 3004; Thirsk, 2838; Pickering, 2555. The elections for the riding are held at the city of York; and the other polling places are Malton, Scarborough, Whitby, Stokesley, Gaisborough, Romaldkirk, Richmond, Askrigg, Thirsk, Northallerton, and Kirby Moorside.

The east riding of the county of York is divided into six wapentakes, the borough of Beverley, and the town and borough of Kingston-upon-Hull. The area of this the smallest of the three ridings, as measured on the map, is 716,160 acres, but the returns from parishes is only 711,360 acres, the difference probably arising from roads and rivers not being included in the computation.

The population at the four decennial enumerations has been found to be, in 1801, 110,992; in 1811, 133,975; in 1821, 153,854; and in 1831, 168,891. At the last of these periods, the males were 82,142, and the females 86,749. The number of families was 36,960, of whom 13,025 were chiefly employed in agriculture, 10,825 in trade, manufactures, and handicraft, and 13,110 were not comprised in either of these classes. The number of males at that time twenty years of age was 41,184. The occupiers of land employing labourers were 3331, and those not employing labourers were 1661; the labourers employed in agriculture were 12,727; the persons employed in manufactures, or in making machinery, were 175; those employed in retail trade or handicraft, as masters or workmen, were 12,017; the capitalists, bankers, professional or other educated men, were 2398; the labourers employed in other than agricultural work were 4663; other males twenty years of age (except servants) were 2627; the male servants twenty years of age were 625, and those under that age 234; the female servants were 6285.

This division of Yorkshire is not marked by any strong or peculiarly striking features, though in some few parts the scenery is good, and, including the sea-views, the prospects near the coast are rather pleasing. The riding may be divided into three parts, as far as regards its productive powers. The first is a tract of level land, extending from the river Humber to nearly the northern boundary of the district. This is in part a rich soil, and, including Holderness, contains some of the best feeding land in this island. The next division is the Wolds, running from north to south, parallel to the former. They are a range of chalky hills, elevated above the level country about 600 feet. The soil is rather a light and chalky loam, in some places mixed with gravel, in others with clay. The extent is from 300,000 to 400,000 acres. Thirty years ago, a very small portion of these Wolds was cultivated; but of late years much of it has been enclosed, and converted into corn-land. The want of good roads is still felt in this part of the country, though the materials for making such roads are abundant and near at hand. The third natural division of the east riding extends from the western foot of the Wolds to the boundaries of the north and west ridings. This tract, commonly called the Levels, is everywhere flat and unpicturesque. The soil is various, but in general of a clayey nature. From Gilberdike to Howden it is very heavy; and though the country is well covered with villages and hamlets, it is extremely dirty, disagreeable, and difficult to travel over.

No part of England shews more proofs of recent agricultural improvements than this riding of Yorkshire. The Wolds have been, by paring and burning, changed from sheep pasture into corn-bearing land. In the low lands great improvements have also been made; extensive tracts, formerly flooded a great part of the year, and scarcely producing any thing but rushes, have been drained, and are covered with such crops of grain that the value of the land has been increased in a most extraordinary degree. The Wolds, in their former state, were very well adapted for breeding horses; but in their present improved state are more profitable as affording pasture for sheep and as growing corn. The warrens for rabbits were formerly very numerous and extensive, but, for the most part, are now more productive by being covered with herbage of a better quality. The farms, especially on the Wolds, and in the southern parts of Holderness, are generally large, renting from L.200 to L.2000 per annum. The climate of the east riding varies considerably. Near the coast, the air is cold, and frequently charged with dense fogs. On the Wolds the cold is more severe, and the snow lies longer; but to the westward of the hills, the air is warm and moist, and tends to produce agues. There are no mines in this riding, and no manufactures, except the spinning of flax, which is performed by the ancient method, and is carried on by all the females in the farm-houses at their leisure hours. The foreign and internal commerce of the riding is wholly carried on through the port of Hull, a place which has thriven during the last forty years as much as any portion of the kingdom. During that period, its population has been more than doubled, and its mercantile shipping and other property have been increased far beyond that ratio.

Extensive docks have been constructed for the reception of vessels, and for affording facilities in the landing and storing of their cargoes. Around these docks a new town has arisen, on what was formerly a swamp, and it surpasses the ancient part in cheerfulness and beauty. The foreign trade of Hull consists in the importation from Russia, Sweden, and Denmark, of naval stores, and the other productions of those countries, and in the exportation to them of the manufactured goods produced in the counties of York, Lancaster, Derby, Chester, and Nottingham, with which the town is connected by means of canal and river-navigation. The same description of trade is carried on between Hull and the ports of Holland and Germany as exists betwixt it and the towns on the Baltic Sea. Although these are the most ancient and the most natural sources of the commerce of Hull, yet to them it is by no means confined. Considerable trade is carried on with the United States of America, with the West Indies, with the ports of the Mediterranean, with Spain and Portugal, and recently with South America. The building and equipping of ships is a source of great employment, and some ships as large as those with 74 guns were built here during the war. Many vessels belonging to Hull shipowners are to be hired for freight, and may be found in almost every part of the globe. The whale-fishery has, from the first years of the discovery of Greenland, been pursued by the inhabitants of Hull, but with pre-eminent success ever since the year 1766, when an individual merchant of that town gave an impulse to that branch of industry, by which its prosperity has been much promoted. In order to promote the internal trade of this division of the county, the town of Goole, on the river Ouse, has, by a recent act of parliament, been made a custom-house and bonding port. Many ships now repair to it to load and discharge cargoes, from its being near to the chief seat of the manufacturing districts, where the population is the most dense, and where is the greatest production as well as consumption of various articles of merchandize. The trade with the interior, by the different rivers that empty their waters into the Humber, and by the canals that connect these rivers with each other, is of an extent which has no parallel in any other part of Europe, where their rivers have a course of navigation of much greater length.

The most interesting objects in this division of Yorkshire are the natural caves at Flamborough Head, York Minster, Howden Church, Kirkham Priory, Bridlington Priory, and Trinity Church in Hull.

The most distinguished seats of noblemen and gentlemen are Wressle Castle, Colonel Wyndham; Birdsal, Lord Middleton; Boynton, Sir William Strickland; Cave Castle, H. B. Barnard, Esq.; Burton Constable, Francis Constable, Esq.; Hotham, R. C. Burton, Esq.; Ragwell, D. Sykes, Esq.; Sledmere, Sir M. M. Sykes, Bart.; Woodhouse, Robert Denison, Esq.; Melburn, Sir Henry Vavasour, Bart.; and Scampson, Sir William St Quintin, Bart.

The election for members of parliament for the east riding is held at Beverley; and the other polling places are Hull, Driffield, Pocklington, Bridlington, Howden, Hedon, and Settrington.

The principal towns and their inhabitants in 1831 were, Hull town, 32,958, but including its very large suburb Sculcoates with 13,468, and Sutton with 4383 inhabitants, the population of the port was 50,809; Beverley, 8302; Bridlington, 4792; Howden, 4531; and Driffield, 2990.

West riding.

The west riding of the county very far exceeds the other two in extent, population, wealth, and activity. It is divided into nine wapentakes; and beside these, a small district is, for election purposes, comprehended in this riding, although some parts of it are situated in the other two ridings. The division of this part, called the Ainsty of the city of York, comprehends the city itself and eighteen other parishes, whose extent is 54,400 acres. Leaving out this Ainsty, the west riding contains 2576 square statute miles, or 1,648,640 acres. The population at the four decennial enumerations was found to be, in 1801, 565,282; in 1811, 655,350; in 1821, 801,274; and in 1831, 976,350. At the last of these periods, the males were 485,812, and the females 490,538; the families were 198,646, of whom 31,188 were chiefly employed in agriculture, 118,733 were engaged in trade and manufactures, and 48,725 not comprised in either of the other two classes. The number of males at that time under twenty years of age was 231,666; the occupiers of land employing labourers were 7096; the occupiers of land not employing labourers were 10,636; the labourers employed in agriculture were 24,502; those persons employed in manufactures, or in making manufacturing machinery, were 74,699; those employed in retail trade or handicraft, as masters or workmen, were 60,109; the capitalists, bankers, professional and other educated men, were 8354; the labourers employed in labour not agricultural, 33,685; other males twenty years of age (excepting servants) 10,366; male servants twenty years of age, 2249, and under twenty years of age, 1025; the female servants were 22,107.

The face of the country furnishes scenes strikingly contrasted. The eastern portion, stretched along the banks of the Ouse, is generally a flat, moist, and marshy district, in some parts fruitful, but in all uninteresting to the tourist. The middle part, as far as Sheffield, Bradford, and Otley, is an undulating country, finely varied, and rising gradually till it reaches the most western portion, which is very rugged and mountainous. Beyond Sheffield, black moors are the only objects, till Blackstone Ledge is reached, on the confines of Lancashire. The western part of Craven presents heaps of rocks and mountains in the most picturesque forms and situations. Pennygant, Wharnside, and Ingleborough, the most conspicuous of these, may be classed among the loftiest mountains in England. According to the Trigonometrical Survey of Colonel Mudge, the height of Wharnside is 2263 feet, of Pennygant, 2270, and of Ingleborough, 2361. Amidst the hilly and mountainous tracts of this riding are many romantic and some sequestered valleys, presenting the most beautiful scenery. The most extensive of these are Netherdale, watered by the Nid, Wharfdale, and the vale of Aire; but many of the smaller vales vie with them in picturesque beauty, and, being generally enclosed, well wooded, and thickly studded with villages and houses, present, from the surrounding eminences, the most enchanting prospects, combining often in the same view the most sublime and the most lively of rural scenery. The roads from Knaresborough or Ripon to Pateley Bridge, from Tadcaster to Otley and Skipton, from Leeds by Bradford and Keighley to Skipton, from Bradford to Halifax, and from Halifax by Dewsbury to Wakefield, unfold some of the finest scenery that can be seen in this island. The climate of this riding is very much varied; in the eastern part, near the Ouse, it is warm and moist; in the middle district the air is sharp, clear, and generally considered healthy; in the western parts the climate is cold, tempestuous, and rainy. The mountains of Craven and the moors near Blackstone Ledge are the most foggy, rainy, and stormy districts in England, though the climate is considered to be salubrious to those of sound constitutions, and the inhabitants have a robust and healthy appearance.

A very great portion of the land of this riding is possessed by small proprietors, although some few noblemen have extensive tracts of land. Most of the occupancies are rather small; none is large; the greater part are less than fifty acres. A great part is kept exclusively in grass, and used for the dairy or for fattening cattle. On the arable lands a greater quantity of wheat is raised than of any other grain. It is mostly of the red kind, and is sown after fallow or turnips, but sometimes on a clover ley. Rye is not cultivated to any great extent. Barley is raised in much less quantities than wheat. Oats are cultivated to a great ex-ent, but little attention is paid to procuring the best seed, though oatmeal forms the chief part of the food of the inhabitants, especially in the more western parts of the riding. Peas are not much raised, nor beans, except on the moorish soils near the Ouse. The turnip husbandry is not so extensively practised as good farming requires; and where it is pursued, it is generally executed in a slovenly and imperfect manner. Great crops of potatoes are raised in the part of the riding below the junction of the river Aire with the Ouse. In the same part of the country much flax is grown, the preparation of the land for which employs the labour of many hands, as does the dressing and preparing the article for market. Rape for making oil, and woad for the dyers, are both cultivated in this riding, but not to any great extent. The waste lands in the west riding were estimated about twenty-five years ago at 400,000 acres, of which 250,000 were considered capable of profitable improvement, and the rest fit for no other purpose but that of planting. Since that period much marsh land has been drained, many commons enclosed, and some bleak hills planted with Scotish firs and larches. Vast improvement has been made on some large tracts of land by the operation locally called *warping*, which is performed by permitting the river, at the highest of the tide, to overflow the land. The rich mud with which the turbid rivers abound is deposited on the surface, and each return of tide increases the earth thus deposited, so that a depth of alluvial soil of fourteen inches has been raised by this means on a field which previously was of very little value. The lands thus improved are so enriched that they will yield abundant crops for several successive years without any manure. The horned cattle, sheep, and horses of the west riding have no distinguishing characteristics, but vary in kind, as in the other two ridings. The same care is not here exercised in improving the breed of horses as in the other two divisions of Yorkshire. The agriculture of this division, if it has not been so rapidly progressive as in some other parts of England, has much improved within the last twenty years; and since, though in that period the population has increased fifty per cent., yet the quantity of corn required from other districts for its subsistence is scarcely greater than at the first period.

In this division of Yorkshire the mines produce great quantities of coal, ironstone, and lead, and vast quarries of limestone. The coal and limestone indeed appear to be almost inexhaustible. The limestone district commences in the tract between Doncaster and Tadcaster, and extends to the western limits of the county. The coal-mines are most numerous between Leeds and Wakefield, and in the neighbourhood of Bradford, Barnsley, and Sheffield, although there are many in other parts of the riding. Iron is found in the greatest quantities near Bradford, and often in the same mine with coal. The best strata of coals are those found under the seams of iron, at a depth from 20[illegible] 240 feet below the surface. The chief mines of lead are at Grassington, a manor belonging to the duke of Devonshire, about ten miles to the westward of Pateley Bridge. It is more owing to the abundant supply of fuel than to any other single cause, that so much manufacturing industry has been developed in this part of Yorkshire, as well as in the neighbouring county of Lancaster.

The great branches of industry which have so rapidly developed and so vastly enriched the west riding of Yorkshire, are the several manufactures that have been established in every part of it. Scarcely a hamlet, or even a house is to be found wherein some part of one or other of the occupations of manufacture, or of those subservient to it, are not seen in different stages of progress. The iron and other hardware goods are produced at Sheffield, Rotherham, and all the villages in the vicinity of those towns. A little to the northward, the large towns of Leeds, Halifax, Bradford, Huddersfield, Wakefield, and the overflowing villages of Almondbury, Kirk-Heaton, Birstall, Dewsbury, with many other places, are devoted to the production of woollen, worsted, cotton, and some linen goods. The progress of the two last fabrics, especially that of linen goods, has been most remarkable since the introduction of power-looms for weaving, and the improvements in machinery for spinning flax. To enumerate the various articles produced by the manufacturers of this most industrious of our districts, would be to copy a catalogue of almost every thing adapted to the use of civilized life.

York.

The most remarkable remains of antiquity in this riding are Selby Abbey, Knaresborough Castle, Fountain's Abbey, Skipton Castle, Bolton Priory, Kirkstall Abbey, Conisbrough Castle, and Roche Abbey.

In proportion to the great extent of the west riding of Yorkshire, it contains more seats of noblemen and gentlemen of distinguished beauty than any other part of Great Britain. Our limits do not allow of our even noticing one-tenth part of them, but the most remarkable are the following: Wentworth House, Earl Fitzwilliam; Harewood, earl of Harewood; Farnley Hall, Walter Fawkes, Esq.; Ripley Castle, Sir William Ingilby; Metheley Park, Lord Mexborough; Gisborne Park, Lord Ribblesdale; Sandbeck, earl of Scarborough; Studley Royal, Miss Lawrence; Ribstone Hall, Sir Henry Goodricke, Bart.; Copgrove, Henry Duncombe, Esq.; Bramham Park, James Lane Fox, Esq.; Wentworth Castle, Henry Vernon, Esq.; Cusworth Hall, William Wrightson, Esq.; Campsall, Bacon Frank, Esq.; Wortley Hall, Lord Wharncliffe; and Topcliffe, Earl de Grey.

The towns of the west riding whose population exceeded 10,000 persons in 1831 were, Leeds, 123,393; Halifax (parish), 109,854; Sheffield, 91,692; Bradford, 23,223; Dewsbury, 19,854; Huddersfield, 19,035; Saddleworth, 15,986; Wakefield, 12,232; Keighley, 11,176; Doncaster, 10,572; Rotherham, 10,417; Barnsley, 10,330.

The riding returns two members to parliament; and the polls are taken at the following places, viz. Wakefield, Sheffield, Doncaster, Snaith, Huddersfield, Halifax, Bradford, Barnsley, Leeds, Keighley, Settle, Knaresborough, Skipton. Pateley Bridge, and Dent.[1]

York, a very ancient city, the capital of the county of the same name. It is 198 miles from London, and 201 from Edinburgh. This city ranks as the second in the kingdom, and is said to have been founded by Ebrancus, 983 years before the Christian era. In form it is very similar to Rome, the river *Ebor* (now called the Ouse) running directly through it. Little is known of its history till the year of our Lord 150, when it was one of the greatest Roman stations in the province, having an imperial palace, a tribunal, and a regular government within its walls, the same as at Rome. In 207 the emperor Severus undertook an expedition to Britain, and lost 50,000 men in defeating the Britons at York. He lived in the palace three years, and died there. His body was burnt on an elevated ground near the city, now called Severus's Hill, and his ashes were sent to Rome. He was succeeded by his sons, Caracalla and Geta, the former of whom murdered the latter in York, and returned to Rome. About a century after, Carausius landed in Britain, and was pro-

York.

claimed emperor at York. He was slain by his friend Alectus, who in his turn was slain by the emperor Constantius, father of Constantine the Great, the latter of whom was born in York in 272, and left it in the fourth century. Constantius died in the palace at York in 307. In the twentieth year of the reign of Constantine, Octavius, king of the Britons, rebelled, but was subdued. Being afterwards joined by the Scots, he defeated the Romans. Britain was then connected with Gaul, and Constantine divided it into three parts, York remaining the metropolis. Constantine soon after this left Britain, and removed the seat of government to Byzantium. The Picts and Scots now rushed upon the Britons, and the latter engaged the assistance of the Saxons. York was consequently the scene of many a deadly conflict, Britons, Saxons, and Danes struggling for dominion, till William the Conqueror came and took possession of the English crown. In all the subsequent national troubles York has had her share, and was particularly conspicuous during the civil wars of Charles the First. The walls, gates, and posterns are to a considerable degree still remaining, and possess high and gratifying interest to the passing stranger. The walls, which are three miles in circumference, have a delightful promenade on the top of them, which commands a beautiful prospect of the surrounding country.

The civil government of the city, under the municipal corporation act, which divides it into six wards, is vested in a mayor (who still retains the title of lord mayor), twelve aldermen, and thirty-five councillors. There are also a recorder, town clerk, and prothonotary. The city gives the title of duke of York to the second son of the sovereign, and returns two members to parliament. The aldermen were formerly justices of the peace, but the magistrates are now appointed by the crown. The situation of York is on a pleasant and healthy plain, through which flow two rivers, the Ouse and the Foss. They are both navigable; but the former is the more important river, and, joining the Humber at no great distance, has a direct communication with the main ocean. There are two markets every week, one on Thursday, the other on Saturday. The latter is the principal, and is always plentifully supplied. There formerly was a division in connection with York, entitled the Ainsty, or County of the City. It was formed by King Richard in 1392. This division included thirty-five towns and villages. In 1837, however, this county of the city being joined to the west riding of Yorkshire, was parcelled into the eastern or York division, and into the western or Tadcaster division; the townships of the former to attend special and petty sessions at the castle of York, those of the latter at Tadcaster. There is another distinct and important division of the city, connected with the cathedral or church of St Peter, and called the Liberty of St Peter. In this division district courts are held, and magistrates preside, in connection with both ecclesiastical and common law.

The minster or cathedral stands the foremost among the public buildings of the city, and is worthy of the attention of every stranger. It is unquestionably the finest Gothic building of the kind in Europe; and in every respect may be pronounced, both as regards the interior and the exterior, truly imposing and magnificent. It was first founded in 626, by Edwin the Saxon king of Northumberland, and through succeeding ages has been enlarged, repaired, and improved, with great taste, and with a uniformity which is highly creditable to all concerned. Our limits will not allow of a minute description, but we may venture to give a brief outline. The nave, from the west end to the door of the choir, is 261 feet long, 109 feet wide, and ninety-nine feet high. The windows of the nave are long, narrow, and pointed, containing representations of some of the apostles, archbishops, &c. Near the south entrance 273 winding steps lead to the summit of the principal tower, from which there is a splendid view of the city and neighbourhood. The body of the nave comprises eight equal arches, the principal part of the western towers being supported by columns. Over the arches runs a curious gallery. On each side, and beyond the choir, are the monuments, many of which are highly interesting. In 741, the minster suffered much by fire. It was repaired, and in 1069, during the siege by the Northumbrians and Danes, was again the victim of that unsparing element. Being rebuilt, it remained the admiration of every beholder, till June 1137, when a tremendous fire in the city consumed it, St Mary's Abbey, and thirty-nine parish churches. It was partly rebuilt in 1171, and was subsequently enlarged. In 1829 the choir was set on fire by Jonathan Martin, a maniac, who hid himself behind a tomb after the evening service, and effected his purpose when all the vergers had departed. He was apprehended, tried, found guilty, and sent for confinement during life to the Criminal Lunatic Asylum, St George's Fields, London, where he died in 1838. The choir was repaired by subscription; and in May 1840, a fire broke out in the south tower of the western front. The flames quickly spread, and the fire continued all night, leaving that tower and the roof of the nave a complete wreck, the very excellent peal of bells having also been destroyed. On inquiry, it was discovered that a person from Leeds, who had been engaged to repair the clock, had been careless with his candle, and that it had communicated with a quantity of combustible matter on the floor, but that no intention to do mischief had ever been entertained. A subscription was again commenced, and the work of restoration is now rapidly advancing. We have already stated that the minster was founded in 626. We may here observe, that Paulinus was the first archbishop, having been instituted the previous year, and that from that time to the present there have been no fewer than eighty-three archbishops; the present being the Hon. Edward Vernon Harcourt, who was translated to the see in 1808. The archbishop of York is primate and metropolitan of England, and has the honour of crowning the queen, and of preaching the sermon at the coronation of the king. There are twenty-three churches in York, in addition to the cathedral; four Methodist chapels; three Independent chapels; two Quakers' meeting-houses; one Catholic chapel, and a nunnery, with extensive premises occupied as a Catholic ladies' school; a Unitarian chapel; and a Primitive Methodist chapel.

Among the charitable institutions of the city, we may mention the County Lunatic Asylum; the Retreat, for the same purpose, established by the Society of Friends; fourteen hospitals or alms-houses for poor widows, &c.; the County Hospital for the sick; the Eye Institution; the School for the Blind; the Blue-Coat Boys' and Grey-Coat Girls' Schools, &c. &c. The other objects of public interest are, the city-walls, the castle, the ruins of Clifford's Tower, the ruins of St Mary's Abbey, the Yorkshire Museum and Gardens, the Assembly Rooms, the public cemetery, &c. York has also its railway stations, very splendidly built, under the direction of George Hudson, Esq., the spirited chairman of the York and North Midland Company. They are connected both with the north, the west, and the south; and the city is altogether improving beyond what has been known in former years. The population of York and its suburbs, according to the census of 1831, amounted to 35,362, viz. 16,510 males, and 18,852 females; the population of the city, exclusively of the suburbs, was 26,260, viz. 11,989 males, and 14,271 females. According to the census of 1841, the population of the city alone is nearly 30,000.

York Cape.

York *Cape*, the north-eastern promontory of New Holland, consisting of a double point, one of which is situateach long. 141. 36. E. and lat. 10. 37. S.; the other in lat. 10. 42. S.

YORK *Islands*, three small islands in the South Pacific Ocean, near York Cape, on the north coast of New Holland.

YORK, *New*. See NEW YORK.

YO-TCHEOU, a city of China, of the first rank, in Hoquang, situated on the great river Yang-tse-kiang, where it connects with the large lake of Tong-ting. It is one of the most populous and trading cities in the empire. The neighbourhood is fertile, and abounds in fruit. Long. 11[illegible]. 35. E. Lat. 29. 23. N.

YOUGANE, a river of Asiatic Russia, in the government of Tobolsk. It rises in the district of Narym, and after passing through a lake of the same name, falls into the Obi.

YOUGHAL, a town in the county of Cork, is situated about 140 statute miles from Dublin, and lies on the shore of a harbour of the same name, into which, at spring-tides, vessels of 400 or 500 tons burthen can enter. It is of great antiquity, and was formerly a place of strength. The old walls in great part remain, and still form, on the summit of the hill to the westward, the boundary of the town. Owing to the very abrupt rise of this hill, the town is confined between it and the water, and can only extend itself in the direction of its length from north to south; but in both these directions it has outgrown its ancient limits, which are there only to be traced by partial remains of the walls. Youghal, notwithstanding its vicinity to Cork, which will probably prevent its ever rising into any great commercial importance, has yet a considerable trade with England, particularly in the export of agricultural produce. It contained, according to the census of 1831, about 9600 inhabitants, and 1200 houses, being, on an average, exactly eight to a house. The increase of population in ten years is supposed to have been about 1000, but is not very accurately known. When the census was taken, there were only six houses building. The greater part of the town belongs to the duke of Devonshire.

YOUNG, EDWARD, born at Upham in Hampshire, in June 1681, was the son of Dr Edward Young, who afterwards became dean of Salisbury. The son was educated on the foundation at Winchester, but he did not succeed to a fellowship at New College, Oxford. In 1703, he was invited by the warden of that college, a friend of his father's, to live at his lodge until he should be qualified to stand for a fellowship at All Souls. He had scarcely availed himself of this acceptable offer, when death deprived him of his host; but he was not long in finding a second patron. From the president of Corpus Christi College, another of his father's friends, he received a summons to join that society, in which he remained until he was nominated by Archbishop Tennison, in 1708, to a law-fellowship of All Souls. His father had now been dead for three years.

In 1712, Young commenced his poetical career as a dauber of greatness, a branch of the art which he pursued with unabated ardour until its close. His first poem was entitled "An Epistle to the Right Honourable George Lord Lansdowne;" one of the twelve worthies whom Queen Anne raised in one day to the dignity of the peerage. If his lordship had half of the talent and virtue ascribed to him by the poet, the nation ought to have been reconciled, upon the catholic principle of supererogation, to the whole batch; but Young became ashamed of this lavish panegyric, as he did of many succeeding ones, and suppressed it. In the same year appeared "The Last Day," part of which had been previously printed in the Tatler. Although he contemplated a period when human grandeur and insignificance must meet on equal terms, he had no apprehension of the speedy consummation of all things, and drew near with becoming reverence to the fountain of sublunary distinction. This poem was inscribed to Queen Anne, but the dedication does not now appear. About the same time he produced "The Force of Religion, or Vanquished Love," founded on the history of Lady Jane Grey and Lord Guilford. It was inscribed to the countess of Salisbury, but, as usual, he denied a place to the dedication among his works. An entire poem on the death of the queen and the accession of George II. he also suppressed. In 1714 he took the degree of LL. B., and five years afterwards that of LL. D. When the Codrington Library was founded in 1716, Young was appointed to deliver a Latin oration, which he dedicated to the ladies of the Codrington family. The selection of Young to compose this harangue speaks favourably of his academical attainments; but it is said that his moments of relaxation were passed in such a manner that he reflected upon them afterwards with little complacency. But whatever was the nature or amount of the indiscretions into which he was betrayed, Dr Tindall, a fellow of All Souls, was unsuccessful in his attempts at making him a convert to infidelity.

Young, Edward.

Young's next patron was the duke of Wharton, "the scorn and wonder of his days." His grace was stained with every vice but that of avarice, which, however, in the eye of Young, was probably the most heinous of all. From a passage in his letter to Richardson on original composition, it is conjectured that Young accompanied the duke to Ireland in 1717. Two years afterwards was brought upon the stage at Drury Lane the tragedy of Busiris. This, or some other play of Young's, is referred to in a number of the Englishman so far back as 1713. It probably lay for six years on the manager's shelf, and was at last taken down in deference to the suggestion of Wharton, or some other competent judge of dramatic writing, whose opinion on that or any other subject it might have been inexpedient to controvert. The first edition of Busiris contains a dedication to the duke of Newcastle, which is only to be found in the copies of that impression.

About this time, Young entered the family of the earl of Exeter as tutor to Lord Burleigh. This employment he quitted at the solicitation of Wharton, who, among other unequivocal tokens of his favour, paid him the compliment of accompanying him to Oxford, where, at his recommendation, he defrayed the expense of a range of buildings then unfinished at All Souls College. In 1721 was acted "The Revenge," the most successful of Young's three tragedies, and the only one that retains possession of the stage. The Revenge is dedicated to the duke of Wharton, whom the poet acknowledges to have suggested the most beautiful incident in the play. His debt of gratitude to Wharton, which he became studious to conceal, he was compelled to divulge in the Court of Chancery under the solemnity of an oath. After the duke's death, it was found that his estates, already sufficiently involved, were threatened with additional perplexity by some unsatisfied claims of Young. The other creditors submitted it to the decision of Lord Hardwicke, whether the arrears of two annuities of one hundred pounds each, granted to Young by the duke, as tokens of his friendship for the poet and esteem for letters in general, considerations not recognized by law, ought not to be regarded as gratuities only, and postponed to their demands, many of which were for money advanced to the deceased nobleman. Being put to his oath, Dr Young swore that he gave up one hundred pounds for life as the tutor of Lord Burleigh, at the pressing entreaty of the duke, who promised to provide more amply for him. It also appeared that in 1721 Wharton had given him a bond for six hundred pounds, to reimburse him for the expenses of a contested election at Cirencester, for which place he had stood candidate, but unsuccessfully, at the duke's request, and in consideration of his refusing to take orders and accept of two livings in the gift of All Souls College. Lord Hardwicke's decision was fatal to the bond, as every man must be supposed, in the estimation of the law, to endeavour to get into parliament with the sole view of serving his country. As to the livings, they were not actually held, and no man can be said to relinquish what he never possessed. But the abandonment of the pecuniary advantages enjoyed by Young in the Exeter family at the time the grant was made by the duke, was pronounced to be a consideration as legal as if money had been paid down. The chancellor therefore directed the arrears of his annuities to be paid out of the funds remaining in the hands of the trustees.

In 1719, he published "A Paraphrase on a part of the Book of Job." Of his seven satires, entitled "Love of Fame, the Universal Passion," we have not seen the original editions, but they probably appeared between the years 1725 and 1728. The satires were followed by "Ocean, an Ode," occasioned by the new king's speech, which recommends the encouragement of seamen to enter the service voluntarily. This production he wisely excluded from the collection of his works. In 1728, he entered into holy orders, and was soon afterwards appointed chaplain to George II. His ode was preceded by some stanzas addressed to the king; and this preferment was probably the reward of his loyalty. If his lyrical poetry improved his fortune, it added nothing to his reputation, for Young's dithyrambics are the worst of all his writings. He now thought it suitable to his new character to withdraw from the players a tragedy entitled "The Brothers," which was already in rehearsal. This play he suffered to be performed many years afterwards, for the benefit of the Society for Propagating Christianity in Foreign Parts; but it met with little success, and he made up the profit to a thousand pounds. Soon after he assumed the character of a clergyman, he published a prose work entitled "A true Estimate of Human Life," and a sermon preached before the House of Commons on the anniversary of King Charles's martyrdom. The title of this discourse is "An Apology for Princes, or the Reverence due to Government." In 1730, Young produced "Imperium Pelagi, a naval Lyric, written in imitation of Pindar's spirit." He did not escape the fate of Icarus; and this nautical Pindaric, one of the many productions which the author refused to acknowledge as his offspring, was justly ridiculed by Fielding in Tom Thumb. During this year he was presented by his college to the rectory of Welwyn in Hertfordshire. In 1731, he married Lady Elizabeth Lee, daughter of the earl of Lichfield, and widow of Colonel Lee. If he received any fortune with this lady, which is probable, he must have been rendered very easy in his circumstances; for, in addition to the emoluments of his living, it is inferred from the following couplet in Swift's Rhapsody on Poetry, which was written soon after this period, that he had an allowance from the court.

> Where Young must torture his invention
> To flatter knaves, or lose his pension.

Wycherley and Addison found little felicity in splendid alliance; but Young was more fortunate in that respect, if we are to estimate the value of his wife by the vehemence of his lamentations for her loss. That mournful event, which happened after ten years' cohabitation, and some other family afflictions that befell him, gave rise to the Night Thoughts, the occasion of which poem, he says in his preface, "was real, not fictitious." Of this work the different portions were published from 1742 to 1744. "The Centaur not Fabulous, in six letters to a friend on the life in vogue," appeared in 1754. This performance is very rhapsodical and declamatory, and there appears in it a prose Lorenzo, who is called Altamont; a proceeding which, to use an illustration of Jeremy Collier, seems like cutting a diamond in two in order to double its value. The Centaur was followed, in 1759, by "Conjectures on Original Composition," in a letter addressed to Richardson, in which are displayed all the fire and fancy of youth. In 1761, he was appointed clerk of the closet to the princess dowager of Wales; and in the year following he published a collection of what he considered the best of his Works, in four volumes duodecimo. In the same year, when he was past fourscore, appeared "Resignation." When the early part of this poem was going through the press, he received the intelligence of the death of Richardson, who was printing it, and with whom he lived on terms of affectionate intimacy. Resignation was written to console Mrs Boscawen for the death of the admiral, but he has dedicated several stanzas to the memory of the novelist. It is touching to hear the veteran poet complain, in the postscript to this production, that some critics had upbraided him with the failure of his powers. This judgment is equally savage and unjust, for Resignation has many stanzas that exhibit all the vigour and originality of his earliest productions. But commendation and reproach were soon to be alike indifferent to him; for, as the dying bard reminds Voltaire, then an old man also,

> One who writes *Finis* to our works
> Was knocking at the gate.

This dreadful summons Dr Young obeyed in April 1765, having reached the eighty-fourth year of his age. He was buried under the communion-table of the church at Welwyn.

It is unnecessary to consider Young in the character of a lyric poet, as, in his attempts to rise to the level of Pindar, he has sunk beneath his own. His fame as a tragedian rests on the Revenge. Thinking a fair complexion less suitable to the European than to the African notions of diabolical malignity, Young has reversed Shakspeare's arrangement in Othello, by making the villain a blackamoor and the noble dupe a white man. Young however has taken nothing from Shakspeare but the general idea of exemplifying the effects of jealousy, stimulated by the machinations of pretended friendship. There is much passion in this tragedy, but there is also much rant and hyperbole. The character of Zanga is a favourite with those performers who are better provided with lungs than brains, and with those spectators who have a keener relish for "sound and fury" than for nice touches of art and masterly strokes of character. Ridicule itself can scarcely heighten some of the extravagancies of this play. Zanga demands an eclipse of the sun on every future anniversary of the day on which he has received corporal punishment from Alonzo; a request which we must own is somewhat more modest than that of Bombardinian in Carey's Chrononhotonthologos, who roars for the immediate dissolution of nature, to testify the divine displeasure at a box on the ear lent him by the king. It is remarkable that Young's three tragedies all end with the obvious expedient of suicide. In the Night Thoughts, faults and beauties are scattered with almost equal prodigality. He is perhaps more deficient in judgment than any poet who has attained to the same degree of eminence. This deficiency appears in the Night Thoughts, by the perpetual blending of sublimity and epigrammatic point; an error into which few poets are in danger of falling, but which we could wish that Young had avoided. There is also a palpable straining after effect in this poem; much labour without art, and much smoke without fire. But if he often offends us by turgid exaggeration and mean conceits, he as often makes us amends by passages of true beauty and grandeur. Next to the Night Thoughts, the Universal Passion is Young's greatest performance. But the effect of these satires is almost neutralized by the lavish applause bestowed upon those to whom they are dedicated. The coarse fondness of Churchill for his pot-companions, and his ruffian swagger to all the world besides, are more edifying, because more disinterested, than the mean partially of the satirist, who pockets his scourge, and is all overacted grimace, at the approach of every titled knave or simpleton. It must however be admitted that if Young often praised the worthless, he never abused the virtuous, which is too often a kindred propensity. Though every line of the Universal Passion sparkles with wit or antithesis, the reader must regret with Swift that the poet was not either more angry or more merry. The greater part both of Young's rhyme and blank verse, for he is the most unequal of all poets, is of a structure more peculiar than pleasing to the ear.

Young, Thomas.

YOUNG, *Thomas*, one of the most distinguished men of the present age, was born at Milverton in Somersetshire on the 13th of June 1773. Both his parents were Quakers, and he was the youngest of ten children. His father bore the same name with himself; his mother was a niece of Dr Brockelsby, an eminent physician in London. His parents, we are informed, were among "the strictest of a sect, whose fundamental principle it is, that the perception of what is right or wrong, to its minutest ramifications, is to be looked for in the immediate influence of a Supreme intelligence, and that therefore the individual is to act upon this, lead where it may, and compromise nothing. To the bent of these early impressions he was accustomed in after-life to attribute, in some degree, the power he so eminently possessed of an imperturbable resolution to effect any object on which he was engaged, which he brought to bear on every thing he undertook, and by which he was enabled to work out his own education almost from infancy, with little comparative assistance or direction from others."

At a very early period, he became an inmate in the family of his maternal grandfather, Robert Davies of Minehead; who, although engaged in mercantile avocations, had cultivated a taste for classical literature, and, without being a very deep or accurate scholar himself, was anxious to inspire his grandson with the love of scholarship. Here he learned to read with fluency when he was only two years old. He was afterwards placed under the tuition of a village schoolmistress; and, during the intervals of his attendance he was occupied with the task of committing to memory various English, and even some Latin poems. It is stated that he easily retained the words, although unacquainted with their meaning; but this mode of exercising his memory can scarcely be regarded as very judicious. Before he had completed his sixth year, he attended the seminary of a dissenting minister. He was next sent to a school at Bristol, where he remained about a year and a half and where, as his biographer remarks, "the deficiency of the instructor appears to have advanced the studies of the pupil, as he here first became his own teacher, and had by himself studied the last pages of the books used, before he had reached the middle under the eye of the master." During the holidays he appears to have derived no small advantage from his acquaintance with one of his father's neighbours, a land-surveyor and land-steward; in whose office he was indulged with the use of mathematical and philosophical instruments, and, what was then of more importance, with the perusal of three volumes of a Dictionary of Arts and Sciences. New sources of knowledge were thus opened to him, and the delight which they afforded seemed to be inexhaustible.

In the year 1782 he was sent to the school of a Mr Thompson at Compton in Dorsetshire. Of this preceptor he was accustomed to speak with great respect, as a man of an enlarged and liberal mind; and under his tuition, he proceeded through the ordinary course of Greek and Latin classics, together with the elementary parts of mathematics. The master possessed a miscellaneous library of moderate extent; and of this he encouraged his pupils to make a free use, allowing them a certain degree of discretion in the employment of their time. This method of proceeding was peculiarly adapted to the taste and exigencies of such a pupil as Thomas Young, whose prematurity of judgment, accompanied with an insatiable thirst of knowledge, qualified him to act as his own preceptor. He rose earlier and went to bed later than his companions, and was thus enabled to devote himself to a surprising variety of pursuits. By the aid of a school-fellow, who had some French and Italian books, he rendered himself tolerably familiar with those languages. "The next study he undertook was botany; and for the sake of examining the plants which he gathered, he attempted the construction of a microscope from the descriptions of Benjamin Martin. This led him to optics; but in order to make his microscope, he found it necessary to procure a lathe. Every thing then gave way to a passion for turning, and science was forgotten for the acquirement of manual dexterity; until, falling upon a demonstration in Martin, which exhibited some fluxional symbols, he was never satisfied till he had read and mastered a short introduction to the doctrine of fluxions. Mr Thompson had left in his way a Hebrew Bible. He began by enabling himself to read a few chapters, and was soon absorbed in the study of the principal oriental languages. At the age of fourteen, when he quitted Mr Thompson's school, he was thus more or less versed in Greek, Latin, French, Italian, Hebrew, Persic, and Arabic; and in forming the characters of those languages, he had already acquired much of the beauty and accuracy of penmanship which was afterwards so remarkable in his copies of Greek compositions, as well as of those subjects connected with the literature of ancient Egypt." Such a statement as this might appear scarcely credible, if we were not possessed of the most unexceptionable evidence that, in every stage of his intellectual career, Young was a very remarkable person.

After he had completed the fourteenth year of his age, he went to reside in the family of Mr David Barclay of Youngsbury in Hertfordshire. Through the intervention of Sir William Watson, it had been arranged that Young and a grandson of Mr Barclay should pursue their studies under a private tutor; but in the mean time the person who had been engaged, found a situation which appeared more advantageous; and Young, who was only about a year and a half older than his companion, began to act as his preceptor. They were afterwards joined by another youth, named Hodgkin, who was of an age somewhat more advanced, and who in 1794 published a work entitled "Calligraphia Græca." Young did not however relinquish his office of tutor, and he found himself capable of directing the studies of both his companions. About this early period of his life, he exhibited symptoms of what was supposed to be incipient consumption; but under the care and skill of Dr Brockelsby and Baron Dimsdale, he recovered his health without suffering any ultimate inconvenience. Nor did his studies experience any material interruption; for we are informed that he was enabled to pursue his labours through nearly the whole duration of his indisposition, and that he merely relieved his attention by what to him answered the purpose of repose, namely, a course of reading in such Greek authors as amused the weariness of his confinement. From 1787 to 1792, he resided during summer in Hertfordshire, and during winter in London. With only the occasional assistance of some masters in the metropolis, he rendered himself perfectly familiar with the great poets and philosophers of antiquity. Of his daily studies he preserved ample notes. "Of the various and conflicting opinions of the ancient philosophers," says Mr Gurney, "he had drawn up a most admirable analysis; and as his reading was not merely the gaining words and phrases, and the minuter distinctions of dialects, but was invariably also directed to what was the end and object of the works he laboured through, it is probable that the train of thought into which he was led in this analysis, was not without its effect in somewhat mitigating his attachment to the peculiar views of the sect amongst whom he had been born. He had acquired a great facility in writing Latin. He composed Greek verses which stood the test of the criticism of the first scholars of the day, and read a good deal of the higher mathematics. His amusements were the studies of botany and zoology, and to entomology in particular he at that time gave great attention.…During the whole term of these five years, he never was seen by any one, on any occasion, to be ruffled in his temper. Whatever he determined on, he did. He had little faith in any peculiar aptitude being implanted by nature for any given pursuits. His favourite maxim was, that whatever one man had done, another might do; that the original difference between human intellects was much less than it was generally supposed to be; that strenuous and persevering attention would accomplish almost any thing; and at this season, in the confidence of youth and consciousness of his own powers, he considered nothing which had been compassed by others beyond his reach to achieve, nor was there any thing which he thought worthy to be attempted, which he was not resolved to master."

It was the wish of Dr Brockelsby that he should devote himself to the medical profession; and having prepared himself by previous reading, he attended Dr Higgins's lectures on chemistry during the winters of 1790 and 1791. He began to perform some simple experiments; but at no period of his life was he much disposed to spend his time, either in devising original experiments, or in repeating those of others. His first appearance as an author is supposed to have been in the Monthly Review for 1791, to which he communicated a short note on gum ladanum, with a verbal criticism on Longinus. The criticism, we are informed, was admitted by Dr Burney to be correct. The critic had only attained the age of eighteen. Towards the close of 1792, he took lodgings at Westminster, where he resided about two years, and pursued his medical studies. He attended the lectures of Baillie and Cruikshank in the Hunterian school of anatomy; and during that period was among the most diligent of the pupils who frequented St Bartholomew's Hospital. He likewise attended courses of lectures on the practice of physic by Dr Crichton and Dr Latham, on midwifery by Dr Clarke and Dr Osborn, and on botany by Sir James Edward Smith.

In 1793 he varied his pursuits by making a tour in the west of England, chiefly with the view of studying the mineralogy of Cornwall. About this period he had been introduced to the duke of Richmond, to whom his uncle was well known; and the duke, then master-general of the ordnance, offered to retain him as his private secretary. Such an appointment might have conducted a young man of his talents to much higher preferment, but he was reluctant to quit the onward path of science. Mr Burke and Mr Windham, to whom he had likewise been introduced by Dr Brockelsby, recommended the plan of entering himself at Cambridge, as a preparation for the study of the law. Burke, it has been stated, "was so greatly struck with the reach of his talents and the extent of his acquirements, more particularly by his great and accurate knowledge of the Greek language, that Dr Young may be considered as in no small degree indebted to the good offices of that eminent statesman, for the extent of interest which his uncle took from this period in his future settlement in life." Adhering to his previous choice of the medical profession, he proceeded to Edinburgh in the autumn of 1794, and there attended the lectures of Black, Monro, and Gregory. He cultivated the acquaintance of the Greek professor, Mr Dalzel, to whom he communicated some notes, as well as a Greek epigram, which were inserted in the second volume of the Collectanea Græca. "He pursued every branch of study in that university with his accustomed intensity, but made the physical sciences more peculiarly the objects of his research. He now separated himself from the society of Quakers; and amidst his medical, scientific, and classical labours, he determined on cultivating some of those arts in which he considered that his early education had left him deficient. But every thing, be its nature what it might, was with him a science; whatever he followed, he followed scientifically. He was extremely fond of music, and of the science of music he rendered himself a master. He had at all times great personal activity, and in youth he delighted in its exercise. But perhaps it may provoke a smile, though too characteristic an anecdote to omit, that in instructing himself in the figure of a minuet, he made it the subject of a mathematical diagram."

Towards the close of the year 1795, he removed to the university of Göttingen. Here he attended lectures on civil and natural history, as well as on different branches of medical science. Of the very extensive and well-arranged library belonging to that university, he did not fail to make an assiduous use. As he was entirely exempted from those dissipations into which so many young men fall, he had sufficient leisure for recreation as well as study; and at Göttingen, as well as at Edinburgh, he diversified his occupations by engaging in various bodily exercises. "He took lessons in horsemanship, in which he always had great pleasure, and practised under various masters all sorts of feats of personal agility, in which he excelled to an extraordinary degree." On the 10th of July 1796 he took the degree of M. D. His inaugural dissertation was printed under the title, "De Corporis Humani Viribus conservatricibus Dissertatio." Gotting. 1796, 8vo. He easily obtained a dispensation from the oath which, in this and other German universities, is very absurdly tendered to candidates, that they will not take the same degree in any other university. Having visited Dresden and Berlin, he now directed his course to England. As he could not be admitted to immediate practice as a licentiate of the College of Physicians, he entered himself as a fellow-commoner of Emanuel College, Cambridge. Dr Farmer, the master, was his uncle's intimate friend. Here he resided three years, and afterwards kept his terms, so as in due time to take his degrees in physic. He did not attend any of the public lectures; nor is it to be supposed that a graduate who had studied at Edinburgh and Göttingen could derive much advantage from an elementary course a Cambridge.

Dr Brocklesby died in the month of December 1797, having bequeathed the larger part of his fortune to his nephew Mr Beeby. The remainder, including his house, library, and pictures, fell to the share of his grand-nephew Dr Young. At the age of twenty-four, he was thus placed in a state of comfortable independence; and after he had completed his necessary residence at college, he established himself in Welbeck-street, and commenced the practice of physic. In 1802 his reputation as a man of science procured him the appointment of professor of natural philosophy in the Royal Institution, where for two years he was associated with Davy. Of the Journals of the Royal Institution, the first volume and a part of the second were edited and chiefly written by Young. During this year he published "A Syllabus of a Course of Lectures on Natural and Experimental Philosophy," containing mathematical demonstrations of the most important theorems in mechanics and optics. Here he announced his great discovery of the general law of the interference of light; that "wherever two portions of the same light arrive at the eye by different routes, either exactly or very nearly in the same direction, the light becomes most intense when the difference of the routes is any multiple of a certain length, and least intense in the intermediate state of the interfering portions; and this length is different for light of different colours."[1] His lectures were too scientific and too profound to be intelligible to any considerable proportion of his auditors; and the matter was so abundant and the style so condensed, that students of a more academical training might frequently have found it extremely difficult to accompany him in his masterly discussions.

During the summer of 1802, he accompanied, in a medical capacity, the present duke of Richmond and his brother Lord George Lennox, in an excursion to France. He attended some of the meetings of the National Institute, and formed an acquaintance with several members of that learned body. On his return to London, he was elected foreign secretary of the Royal Society, of which he had been admitted a fellow at the age of twenty-one. This office he retained during the remainder of his life, and was always one of the most leading and most efficient members of the council. In the year 1804 he married Eliza the daughter of James Primrose Maxwell, Esq. of Cavendish-square; and the union is said to have been attended with uninterrupted happiness. His wife, who still survives him, had no children. His scientific attainments have not been overlooked by Arago. After his marriage, he thought it expedient to resign his professorship, in order to present the appearance of a more entire devotion to the practice of physic; but it was impossible for such a man to withdraw himself from the pursuits of science and literature. He now occupied himself in preparing for the press a most elaborate and valuable work, "A Course of Lectures on Natural Philosophy and the Mechanical Arts." Lond. 1807, 2 vols. 4to. This work was the result of assiduous and energetic labour for the space of five years; two of which were devoted to the preparation of the lectures as delivered, and three more to the examination and arrangement of the great body of references contained in the second volume, as well as to the improvement of the texture of the work, particularly where new materials, or new experiments, or repeated investigations, seemed to render it necessary. In a commercial point of view, the book was by no means successful. The booksellers became insolvent soon after its appearance, nor was the sale sufficient to defray the expense of the publication. Of the merits of a work so truly scientific, very few readers were competent to form an opinion; and, according to the author's own impression, his labours first began to be generally appreciated by the philosophers of the continent.

In 1808 Dr Young was admitted a fellow of the College of Physicians; and in 1810 he was elected physician to St George's Hospital. For fourteen successive years from the period of his marriage, he passed his winters in the metropolis and his summers at Worthing. We are informed that his practice, though respectable, was never very extensive, and that he was averse to some of the ordinary methods by which practice is acquired. "He was not," says Dr Pettigrew, "a popular physician. He wanted that confidence or assurance which is so necessary to the successful exercise of his profession. He was perhaps too deeply informed, and therefore too sensible of the difficulty of arriving at true knowledge in the profession of medicine, hastily to form a judgment; and his great love of and adherence to truth made him often hesitate where others felt no difficulty whatever in the expression of their opinion. He is therefore not celebrated as a medical practitioner, nor did he ever enjoy an extensive practice; but in information upon the subjects of his profession, in depth of research into the history of diseases, and the opinions of all who have preceded him, it would be difficult to find his equal."[2] Dr Young was likewise connected with the Middlesex Hospital, where for two seasons he delivered a course of lectures, which, according to his own statement, "were little frequented, on account of the usual miscalculation of the lecturer, who gave his audience more information in a given time, than it was in their power to follow." He printed "A Syllabus of a Course of Lectures on the Elements of the Medical Sciences." Lond. 1809, 8vo. This was followed by a more elaborate publication, "An Introduction to Medical Literature, including a System of Practical Nosology." Lond. 1813, 8vo. A second edition appeared in 1823. This volume is another monument of his indefatigable research, as well as of the sagacity and judgment which he exerted in all his investigations. After an interval of two years, he produced another professional work, which greatly extended his reputation, "A practical and historical Treatise on Consumptive Diseases." Lond. 1815, 8vo.

His separate publications exhibit but a small portion of his literary labours. His contributions to periodical works, and to the transactions of various societies, were very numerous, and not a few of them were very elaborate. At the suggestion of his intimate friend George Ellis, he was induced to lend his powerful aid to the Quarterly Review. His first undertaking was merely to furnish notices of medical publications; but he immediately began to include other branches of science, nor did he overlook some of his favourite branches of literature. His review of Adelung's Mithridates, inserted in the tenth volume, would alone have been sufficient, had he left no other monument of his ingenuity and learning, to procure him the character of an uncommon man. To the Imperial Review, which ran a shorter course, he likewise contributed a variety of articles. Dr Young was one of the many distinguished individuals who appeared as contributors to the Supplement to the Encyclopædia Britannica. His articles, or portions of articles, sixty-three in number, relate to subjects not a little dissimilar in their nature. Most of them are reprinted in the present work, and, unless where his name is expressly mentioned, they are generally distinguished by the signature L. L. He supplied several biographical notices, not only of scientific men, but likewise of classical scholars, among whom are Bryant, Porson, and Wakefield. In his excellent notice of Porson (vol. xviii. p. 452, a.) we must here request the reader to correct a Greek quotation, which is printed in such a manner as to be altogether unintelligible. It ought to stand thus: ζωρὸν μετροῦσα θυῶεν πορφυρέης Λέσβιον ἐξ ὑέλου. He had previously written several papers on the very difficult and obscure subject of hieroglyphics; and in the article EGYPT he now presented the result of his investigations. In this bewildering field of literature, the only ancient guide is Horapollo, whose work Dr Young describes as puerile, and "much more like a collection of conceits and enigmas than an explanation of a real system of serious literature."[3] The labours of many different scholars had left the subject of hieroglyphics almost as obscure as they found it, when Young and Champollion,[1] nearly at the same time, commenced their more fortunate enquiries. Dr Young afterwards published a separate work, under the title of "An Account of some recent Discoveries in Hieroglyphical Literature, and Egyptian Antiquities: including the author's original Alphabet, as extended by Mr Champollion, with a Translation of five unpublished Greek and Egyptian Manuscripts." Lond. 1823, 8vo. He was likewise the editor of "Hieroglyphics, collected by the Egyptian Society." Lond. 1823, fol. This is a collection of lithographic plates, executed at the expense of the society; but the subscriptions being insufficient to defray it, the work was transferred to the Royal Society of Literature, and he still continued his superintendence. His unrivalled merits in this difficult province have been so fully estimated in the article HIEROGLYPHICS, that it would here be superfluous to resume the subject.

[3] Young's Account of some recent Discoveries in Hieroglyphical Literature, p. 3. See likewise Mr Salt's Essay on Dr Young and M. Champollion's Phonetic System of Hieroglyphics, p. 44. Lond. 1825, 8vo. Orus, Horus, Horus Apollo, or Horapollo, is said to have been an ancient Egyptian, and to have written in his native language. The treatise which bears his name is professedly a translation from the Egyptian into the Greek tongue by a certain Philippus, who is otherwise unknown. It was first printed by Aldus, in a volume containing several other reliques of Greek literature. Venet. 1505, fol. The subsequent impressions are not numerous. An elaborate edition has recently been published by Leemans: "Horapollinis Niloi Hieroglyphica. Edidit, diversorum codicum recenter collatorum, priorumque editionum varias lectiones, et versionem Latinam subjunxit, adnotationem, item hieroglyphicorum imagines, et indices adjecit Conradus Leemans, Phil. Theor. Mag. Lit. Hum. Doct." Amst. 1835, 8vo. The Greek text, accompanied with an English version, has still more recently ap-

Early in the year 1817, Dr Young had been called to Paris for the purpose of attending a patient; and he was much gratified by the reception which he there experienced from the most distinguished men of science. With Alexander von Humboldt, Cuvier, Arago, Biot, and Gay-Lussac, he had previously become acquainted in England. With such individuals as these it was a great pleasure to renew his personal intercourse; and in the summer of the same year he again revisited Paris, and resided there for a few weeks. In 1818 he was appointed one of the commissioners for taking into consideration the state of the weights and measures employed in Great Britain. In this commission, issued under the privy seal, he was associated with Dr Wollaston, Captain Kater, Mr Davies Gilbert, Sir Joseph Banks, and Sir George Clerk. He acted as secretary to the board, of which he appears to have been the most efficient member; for to the three Reports presented to parliament, he furnished both the scientific calculations, and the account of the various weights and measures in common use. Before the close of this year, he was appointed secretary to the Board of Longitude, with the charge of the supervision of the Nautical Almanac. In the act of parliament under which this appointment took place, he was nominated one of the commissioners. "This appointment was to him a very desirable one, though the labour in which it involved him was great, as his anxiety to increase his medical practice henceforth ceased, and it made that the business of his life which had always been his inclination." After a period of ten years, the board was suppressed; but the Admiralty was permitted to retain the officer entrusted with the calculations of the almanac. The assistance of men of science was soon found to be necessary in other departments connected with the Admiralty; and a new council of three members, consisting of Dr Young, Captain Sabine, and Mr Faraday, was entrusted with those services which had previously been performed by the board.

After his appointment to the office of secretary, he discontinued his summer residence at Worthing. During the summer of 1819 he proceeded to Italy, where he spent about five months, and visited all the most remarkable cities. One object of peculiar interest was the examination of the Egyptian monuments preserved in that country. He returned homeward by Switzerland and the Rhine. He afterwards published a work entitled "Elementary Illustration of the Celestial Mechanics of La Place; with some additions relating to the Motion of Waves and of Sound, and to the Cohesion of Fluids." Lond. 1821, 8vo. This volume, and the article TIDES reprinted in the present work, he was disposed to regard as containing the most fortunate of the results of his mathematical investigations. During the ensuing year he paid another visit to Paris; and in 1824 he made an excursion to Spa and to Holland. On his return, he undertook the scientific direction of a company for life-insurance. The rage for joint-stock schemes had about this period attained its utmost height; but he declined all participation in the commercial part of the speculation, and restricted himself to his own mathematical department. He was thus induced to deviate into a new path of enquiry; and, in 1826, he contributed to the Philosophical Transactions "A Formula for expressing the Decrement of Human Life;" and to Brande's Philosophical Journal, a "Practical Application of the Doctrine of Chances." He had the satisfaction of witnessing the prosperity of the company with which he had formed this connexion.

In the course of the preceding year, he had removed from Welbeck-street to a house which he had built in Park-square; "where he continued to reside during the remainder of his life, and where, in a situation to which he was extremely attached, he led the life of a philosopher, surrounded by every domestic comfort, and enjoying the pleasures of an extensive and cultivated society, who knew how to appreciate him. He expressed himself as having now attained all the main objects which he had looked forward to in life as the subject either of his hopes or his wishes." In 1827 he was elected one of the eight foreign members of the Royal Institute of France. But the life which had thus been so prosperous and so honourable, was not destined to be long. With the exception of the consumptive tendency which he had exhibited at an early period, his health had not been impaired by serious illness a single day. In the summer of 1828 he made an excursion to Geneva; and on his return, his friends began to perceive symptoms of decaying strength. The business entrusted to the Board of Longitude having about this time been transferred to the new council, he was subjected to the labour of drawing up various reports, when the state of his health rendered this an exertion to which he was no longer equal. From the month of February ensuing, he had repeated attacks of what he supposed to be asthma. In the beginning of April, he experienced great difficulty of breathing; and this symptom was accompanied with a habitual though not copious discharge of blood from the lungs. "Though thus under the pressure of severe illness," says Mr Gurney, "nothing could be more striking than the entire calmness and composure of his mind, or could surpass the kindness of his affections to all around him. He said that he had completed all the works on which he was engaged, with the exception of the Rudiments of an Egyptian Dictionary, which he had brought near to its completion, and which he was extremely anxious to be able to finish. It was then in the hands of the lithographers, and he not only continued to give directions concerning it, but laboured at it with a pencil when, confined to his bed, he was unable to hold a pen. To a friend who expostulated with him on the danger of fatiguing himself, he replied it was no fatigue, but a great amusement to him; that it was a work which, if he should live, it would be a satisfaction to him to have finished, but that if it were otherwise, which seemed most probable, as he had never witnessed a complaint which appeared to make more rapid progress, it would still be a great satisfaction to him never to have spent an idle day in his life....In the very last stage of his complaint, in the last lengthened interview with the writer of the present memoir, his perfect self-possession was displayed in the most remarkable manner. After some information concerning his affairs, and some instructions concerning the hieroglyphical papers in his hands, he said that, perfectly aware of his situation, he had taken the

peared, under the title of "The Hieroglyphics of Horapollo Nilous, by Alexander Turner Cory, Fellow of Pembroke College, Cambridge." Lond. 1840, 8vo.

[1] See the work of Klaproth, Examen critique des Travaux de feu M. Champollion sur les Hiéroglyphes. Paris, 1832, 8vo.

sacraments of the church on the day preceding; that whether he should ever partially recover, or whether he were rapidly taken off, he could patiently and contentedly await the issue."[1] With some slight variations, his illness continued till the morning of the tenth of May 1829, when his strength having been gradually exhausted, he expired without a struggle, before he had completed the fifty-sixth year of his age. The fatal disease was ascertained to be an ossification of the aörta, exhibiting the appearance of having been in progress for many years. His intellectual labours had been so great and so incessant as to produce the indications of an age much more advanced. His mortal remains were deposited in a vault belonging to his wife's family, in the church of Farnborough in Kent.

The work which had engaged his attention during the last days of his life, was published under the title of "Rudiments of an Egyptian Dictionary in the Ancient Enchorial Character; containing all the Words of which the sense has been ascertained. Intended as an Appendix to Mr Tattam's Coptic Grammar." Lond. 1830, 8vo. It appears in the same volume with the work of Mr Tattam, "A compendious Grammar of the Egyptian Language, as contained in the Coptic and Sahidic Dialects." This learned fellow-labourer, it may not be improper to add, has continued to prosecute his researches in the same department, and has subsequently produced a "Lexicon Ægyptiaco-Latinum." Oxonii, 1835, 8vo.

Among other advantages, Dr Young possessed that of a handsome person and prepossessing appearance. His manners were polished and even elegant, though perhaps exhibiting a very slight tendency to a scholar-like preciseness. Such at least was the impression received by the writer of the present imperfect notice. By his friend and biographer he is described as "a man in all the relations of life, upright, kind-hearted, blameless. His domestic virtues were as exemplary as his talents were great. He was entirely free from either envy or jealousy; and the assistance which he gave to others engaged in the same lines of research with himself, was constant and unbounded. His morality through life had been pure, though unostentatious. His religious sentiments were by himself stated to be liberal, though orthodox. He had extensively studied the Scriptures, of which the precepts were deeply impressed upon his mind from his earliest years; and he evidenced the faith which he professed, in an unbending course of usefulness and rectitude." Of his merits as a man of science, it may here be sufficient to state that a very high estimate has been formed by Arago.[2] His literary attainments were equally solid and extensive; nor would it be easy to mention another individual of the present age worthy in all respects of being compared with Thomas Young. (x.)

YOUNG NICK'S HEAD, a cape on the east coast of New Zealand, so called from the boy Nicholas Young, on board the Endeavour, who discovered it in 1769. It forms the south-west point of Poverty Bay.

YOWRY, a small island in the Eastern Seas, near the north coast of New Guinea. Long. 130. 45. E. Lat. 0. 15. S.

YPRES, a circle of the province of West Flanders, in the Netherlands, extending over 330 square miles, divided into seven cantons, and those into forty-six communes, with 96,800 inhabitants. The capital is the city of the same name. It stands on the river Yperle, by which it has a communication with the sea at Nieuport. It is in a fruitful district, is fortified and well built, with a fine market-place and most magnificent town-house. There is a college, a cathedral, four other churches, and several convents. There was formerly much more trade than at present, consisting chiefly in linens. It now contains 16,500 inhabitants. Long. 2. 47. E. Lat. 50. 51. 10. N.

YU, two rivers of China; one rises in Honan, twelve miles north of Pi-yang, and joins the Hoai, twenty miles east-south-east of Sin-tsai. The other rises about twenty-six miles west from Ngan-fou, in Kiang-see, and runs into the Kan-kiang, seven miles north-north-east of Lin-kiang. It is also the name of several cities of the second rank.

YUCATAN. See MEXICO. Since that article was written, the state of Yucatan has separated itself from the Mexican confederation, and having declared itself independent, has established a constitution on the most liberal principles, religious, political, and commercial.

YUEN, a city of China, of the second rank, in Hoo-quang. Long. 109. E. Lat. 27. 23. N.

YUEN-KIANG, a city of China, of the first rank, in Yunan, on the Hoti river, in a mountainous but fertile country, abounding with silk. Long. 101. 44. E. Lat. 23. 37. N.

YUEN-TCHEOU, a city of China, of the first rank, in Kiang-see, on the borders of an agreeable little lake. Alum and vitriol are produced in the neighbourhood. Long. 114. E. Lat. 27. 50. N.

YUEN-YANG, a city of China, of the first rank, in Hoo-quang, on the river Han, and on a plain encompassed by mountains, where tin is found. It is 517 miles south-south-west of Peking. Long. 110. 29. E. Lat. 32. 50. N.

YUNAN, a province of China, situated on its south-western frontier, bounded on the north by Sechuen and Tibet, on the east by Quang-see and Koei-tchoo, on the south by Laos, and on the west by Ava and Pegu. It is about 300 miles in length by 250 in breadth, and though mountainous, it is one of the most fertile and opulent in China, being well watered both by rivers and lakes. Its produce is gold, copper, and tin, amber, rubies, sapphires, agates, pearls, precious stones, marble, musk, silk, elephants, horses, gums, medicinal plants, and linen. It has a vast commerce, contains twenty-one cities of the first class, and fifty-five of the second and third. The population is estimated by Sir George Staunton at eight millions.

YUN-HING, a city of China, of the first rank, in Honan, watered by a river called Yuho. The country within its district is large, and is watered by several rivers, which render the soil very fruitful. Long. 113. 52. E. Lat. 33. N.

YUN-LEAN-HO, a canal of China, formed of the river Pey-ho, or rather the river itself made navigable from Hiam-ho to Tien-tsin, in the province of Pe-tche-lee, for the purpose of conveying corn towards Tong-tcheou and Peking.

YUNSHAN, the territory lying between the eastern limits of the Birman empire and China, of which very little is known, even to the Birmans.

YUNTAI, an island near the coast of China, in the Eastern Seas, thirty miles in circumference, about two miles and a half from the continent. Long. 119. 19. E. Lat. 34. 35. N.

---

[1] Gurney's Memoir of the Life of Thomas Young, M. D., etc. p. 41. Lond. 1831. 8vo. To this Memoir he has subjoined "A Catalogue of the Works and Essays of the late Dr Young," which had been prepared by himself in 1827.

[2] Eloge Historique du Docteur Thomas Young, par M. Arago: Mémoires de l'Académie Royale des Sciences de l'Institut de France, tom. xiii. p. lvii. Of the life and scientific labours of Dr Young, an ample and satisfactory account is expected from the able pen of Dr Peacock, dean of Ely.

Z.

Z, the twenty-fifth and last letter, and the nineteenth consonant, of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time. This letter has been reputed a double consonant, having the sound *ds;* but, some think, with very little reason; and, as if we thought otherwise, we often double it, as in *puzzle*, *muzzle*, &c. Among the ancients, Z was a numeral letter, signifying 2000; and with a dash over it thus, $\overline{Z}$, signified 2000 times 2000, or 4,000,000.

In abbreviations this letter formerly stood as a mark for several sorts of weights: sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it has in earlier times been used to express the third part of an ounce, or eight scruples. ZZ were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinziber or ginger.

ZAARA, Zahara, or *the Desert.* See Sahara.

ZAB, a river of Kurdistan, which rises in the mountainous country to the east of the Tigris. It falls into the Altun Su, or Golden Water, about 150 miles north of Bagdad, on the road to Mosul, and the united streams afterwards reach the Tigris.

ZABULON, one of the twelve tribes of Israel; bounded on the north by the tribes of Asher and Naphthali; on the east by the Sea of Galilee; on the south by the tribe of Issachar or the brook Cison, which ran between both; on the west by the Mediterranean; so that it touched two seas, or was bimarous.

ZAFRA, a small town of Asiatic Turkey, in the government of Marasch, fifteen miles west of Tarsus. There is another town of the same name in the government of Trebisond, fifty miles north-west of Trebisond.

ZAIRE, a river of Southern Africa, likewise called Congo. See Congo.

ZALEUCUS, a famous legislator of the Locrians, and the disciple of Pythagoras, flourished 500 years B. C. He made a law, by which he punished adulterers with the loss of both their eyes; and his son offending, was not absolved from this punishment; yet, to shew the father as well as the just lawgiver, he put out his own right, and his son's left eye. This example of justice and severity made so strong an impression on the minds of his subjects, that no instance was found of the commission of that crime during the reign of the legislator. It is added, that Zaleucus forbade any wine being given to the sick, on pain of death, unless it was prescribed by the physicians; and that he was so jealous of his laws, that he ordered, that whoever was desirous of changing them, should be obliged, when he made the proposal, to have a cord about his neck, in order that he might be immediately strangled if those alterations were esteemed no better than the laws already established. Diodorus Siculus attributes the same thing to Charondas, legislator of the Sybarites.

ZAMA, an ancient town of Chamane, a district of Cappadocia, of unknown situation. Another Zama, of Mesopotamia, on the Saocoras, to the south of Nisibis. A third, of Numidia, distant five days' journey to the west of Carthage. It was the other royal residence of the kings of Numidia, hence called *Zama Regia.* It stood in a plain, was stronger by art than nature, richly supplied with every necessary, and abounding in men, and every weapon both of defence and annoyance. This town is remarkable for the decisive battle fought between the two greatest commanders in the ancient world, Hannibal the Carthaginian, and Scipio Africanus.

ZANGUEBAR, a region of Africa, lying on the eastern coast, between three degrees of north latitude, and eighteen south. It includes several petty kingdoms, in which the Portuguese have various settlements. The inhabitants, except those converted by the Portuguese, are all Mahommedans or idolaters; and the latter much the more numerous. The names of the principal territories are, Mombaza, Lamon, Melinda, Quiola, and Mozambique. The Portuguese built several forts in Mombaza and Mozambique, and there settled several colonies.

ZANTE. See Ionian Islands.

ZAPATA, a kind of feast or ceremony held in Italy in the courts of certain princes, on St Nicholas's day. People hide presents in the shoes or slippers of those to whom they would do honour, in such a manner as may surprise them on the morrow when they come to dress. This is done in imitation of the practice of St Nicholas, who used in the night-time to throw purses of money in at the windows to furnish marriage-portions to poor maidens.

ZARAGOZA, a city of Spain, in the corregimiento of that name, and the capital of the ancient kingdom of Aragon. It was built by the Roman colonists, and bore the name of Cæsar Augusta. It is about 175 miles from Madrid, and the same distance from Valencia. It stands on the right bank of the Ebro, over which are two bridges connecting the city with the suburbs. The streets are narrow, except one, the Cozo or Cosso, which runs the whole length of the town; and the houses are old, and, though not lofty, are highly ornamented. Zaragoza is the seat of an archbishop, and, besides a cathedral, had seventeen churches, and forty religious houses of different orders, for males and for females. One of the churches, called Our Lady of the Pillar, was the most celebrated in Spain, and, except that of Loretto, in Europe, from the number of pilgrims that every year resorted to it for devotional purposes. On a lofty pillar of jasper is an image of the holy virgin, the great object of adoration, and excitement to delusive feelings of devotion. In the rich and highly cultivated plain that surrounds the city, stand the ancient palace of the Alguferia, the residence of the kings of Aragon, and several monasteries.

A little below the city, that magnificent work the Canal of Aragon joins the river Ebro, which runs about 100 miles parallel to that river, and connects the provinces of Aragon and Navarre with the Mediterranean Sea. It is designed to assist commerce as a means of conveyance, and to supply to agriculture water for irrigating the fields. This canal has been constructed by the eminent civil engineer Don Ramon Pignatelli, and 3,250,000 livres had been expended when it was stopped. Had it been continued to Biscay, it would have brought the Mediterranean and the Atlantic Seas into commercial contact.

The great celebrity of this city arises from the firm defences made during two sieges, in the years 1808 and 1809, when the courageous and enduring spirit of an undisciplined and ill-armed population was assailed by two successive French armies, furnished with all that science could contribute to the art of war, and commanded by some of the most distinguished officers belonging to the armies of France.

From the latest accounts of this city, the actual population scarcely amounts to 40,000 persons, though it is capable of housing 150,000.

ZEALAND, one of the provinces of the kingdom of Denmark. It comprehends the large island of that name, in which is Copenhagen, the capital of the kingdom, and the smaller islands of Amak, Saltholm, Syeroe, Omoe, and Aggersoe, near to it, and also the more extensive ones of Moe, Samsoe, and Bornholm. The island is 2790 square miles in extent, and the whole province 3140.

The island is generally a level plain, with few elevations but is deeply penetrated by arms of the sea, called fiords, which in appearance are lakes, and, where their shores are clothed with woods, present pleasing prospects. The soil is evidently composed of coral and mussel-shells, which the course of ages has converted into calcareous substances. This is mixed with sand, pebbles, clay, and vegetable matter, and thus is highly fertile in many parts, especially on the south and south-east coasts. It yields moderate crops of wheat and rye, but better of barley and pulse. Flax, rape, and some tobacco, are cultivated; but neither these plants nor the grain is sufficient for the consumption. Butter and cheese, with swine's flesh, are more abundant, and indeed the dairy is an important branch of rural application. The fishery on the coasts is, next to agriculture, the chief occupation. The chief trade is in the capital, Copenhagen; and the other towns are inconsiderable, except Roskilda, Elsineur, and Kioge, in the former of which, in the cathedral, is the burial-place of the royal family. The climate of the island is very variable, especially in winter, and not generally favourable to longevity. The population in 1834 amounted to 464,607, being an increase since 1801 of 28 per cent.

ZEALAND, a province of the kingdom of Holland, which, besides the group of islands formed in the river Scheldt, includes a section of the continental dominions. The province extends in north latitude from 51° 14′ to 51° 45′ and in east longitude from 3° 8′ to 4° 2′. The whole extent is 667 square miles. The surface is flat and low, being but a few feet higher than the water at half-flood tide. As the shore in this province is not, as in some others, protected against the sea by sand-hills or downs, it has been found necessary to defend it by artificial walls, which are from fourteen to sixteen feet in height, with a gentle declivity towards the sea, and nearly perpendicular on the land side. In front they have placed stakes, which, by dividing the waves, in some measure break their force.

The soil of the island is uniformly rich; being clayey, with a fruitful loam, which requires but little manure, and scarcely ever disappoints the hopes of the husbandman. All kinds of corn and green crops come to perfection in these soils. As agriculture is thus productive, there is every year a surplus of food. The wheat, especially in South Beveland, is considered the best in the kingdom; besides which, much rye is cultivated, and likewise barley, which is of peculiar excellence for malting. Beans and pease are raised in great quantities, chiefly for export; and flax is raised to a great extent both for home use and for foreign trade. Madder is a valuable article of cultivation, and that of the island Schouwen is in the highest estimation. The annual export of this dye amounts to more than 20,000 quintals. The dairies yield large portions of good cheese and butter, and fatten swine, whose flesh, when pickled, furnishes provision for the shipping. The sheep are small, and their wool indifferently fine. The horses are a heavy breed, but strong and tolerably hardy.

The climate is heavy, moist, and variable, and for strangers very unhealthy, but much less so for the natives. It snows and freezes much less on the islands than on the mainland.

The inhabitants consisted in 1833 of 67,059 males, and 70,203 females; thus making together 137,262, of whom 43,145 were found in the cities, and 94,117 in the villages. The divisions of religion shew 100,747 Protestants, 36,060 Roman Catholics, and 455 Jews. The population had increased in 1837 to 145,542; and, on the whole, they are supposed to be in as easy circumstances as any in the kingdom. They adhere to their ancient customs, manners, and dress, and speak a peculiar dialect of Dutch, nearly approaching to that of the Flemings. Many of them are engaged in fishing and other marine pursuits. Their manufacturing industry is chiefly applied to spinning fine linen yarn; and there are many distilleries, breweries, oil-mills, limekilns, salt-refineries, and establishments for ship-building. The capital is the city of Middelburg, in the island of Walcheren, containing 14,700 inhabitants.

ZEALAND, NEW.

In the article AUSTRALASIA (vol. iv. p. 215) we have already given a general description of New Zealand, sufficiently comprehensive for the degree of importance which then belonged to the subject. But within the last two years the New Zealand group has been made the theatre of so extraordinary a movement in colonization, that we are induced to devote to the subject a greater space than would otherwise have been justifiable; and we avail ourselves of a license which the name furnishes, to give in this place a brief history of the recent proceedings for the colonization of these interesting islands.

It may, in the first place, be proper to describe the complete revolution which of late years has taken place, both in the practice of colonization, and in the state of public opinion respecting it.

Until within a very recent period, it was the custom of the British government to give away the waste lands in our colonies to all applicants. System there was none; but several hundred different modes of granting land have at different times been recognised by the government, all of them however agreeing in rendering land as cheap as possible. Every labouring man who applied for land had a certain number of acres allotted to him: although conditions were sometimes imposed, they were easily evaded; and, in practice, land may be said to have been given unconditionally away. The effect of this upon men of the labouring class may easily be conceived. In the country which they had just quitted, to own land was to be great and powerful. The idea of wealth was inseparably united with that of land; and the prevailing desire of nearly every emigrant is to become an independent freeholder. The consequence of this very natural desire was, that no man would labour for hire, but would rather content himself with scratching up the soil by the aid of some rude help to labour, which scarcely deserved the name of capital.

Now, where labour cannot be obtained, capital is not very prone to establish itself; and even if it did perchance find its way into such a country, a considerable portion of it must have remained unproductive, and must frequently have rotted for want of hands to use it. In a country, in short, where the temptation to take land is very great, the capitalist can offer to the labourer no inducement to labour for hire, equal in force to the inducement to occupy land. On the other hand, the land-owning labourer cannot present to the capitalist's mind any motive to induce him to part with his capital. Thus that degree of co-operation between the capitalist and labourer, which effects such wonders in this country, cannot exist in a country where land is excessively cheap; and production, wanting that co-operation, is reduced to the minimum. The labourer certainly gets the whole produce of the soil; he has nothing to pay to a capitalist for the use of his implements; but then it is a very small whole that he secures. In like manner, the capitalist may perhaps felicitate himself on having nothing to pay for labour. In his turn he secures all the produce of his fields, but that all is extremely scanty.

Another evil of the excessive cheapness of land is, that there can be no combination of labour wherever it exists. There may be some degree of skill, together with many other valuable qualities, generated by the labourer's habit of independent exertion; but that exertion is isolated, and results which require the combined exertion of numbers can never be attained.

It must be further evident, that where each individual possesses a considerable breadth of land, only a small portion can generally be brought under cultivation. The cultivated spots are therefore scattered over a vast extent of country; dispersion of population necessarily exists; and barbarism prevails throughout the country. In a country so circumstanced, a man scarcely knows his neighbour; schools cannot be maintained; and the very rudiments of the social state become extinguished, if indeed they ever appeared.

Into a country in such a condition, capital would speedily cease to flow, because there would be nothing to attract it; and the country would soon exhibit the phenomenon of a population of pauper land-owners. There would be no colonization, properly so called; there would simply be the emigration of masses.

The last colony deliberately established on the principle, if such it can be called, of rendering land as cheap as possible, was that of the Swan River in 1829. Mr Peel was the first grantee. He took five hundred thousand acres, and marked out his land around the port. This, says Mr Wakefield, in his evidence before the Waste-Land Committee in 1836, was as much as to say, "this is a desert; no man shall come here; no man shall cultivate this land." Other persons took large blocks; and so complete was the dispersion, that the settlers could not find each other. "That," continues Mr Wakefield, "was why some people died of hunger; for though there was an ample supply of food at the governor's house, the settlers did not know where the governor was, and the governor did not know where the settlers were. Then, besides the evils resulting from dispersion, there occurred what I consider almost a greater one, which is the separation of the people, and the want of combinable labour. The labourers, on finding out that land could be obtained with the greatest facility, the labourers taken out under contracts, under engagements which assured them of very high wages if they would labour during a certain time for wages, immediately laughed at their masters. Mr Peel carried altogether about three hundred persons, men, women, and children. Of these, about sixty were able labouring men. In six months after his arrival, he had nobody even to make his bed for him, or to fetch him water from the river. He was obliged to make his own bed, and to fetch water for himself, and to light his own fire. All the labourers had left him. The capital therefore which he took out, viz. implements of husbandry, seeds, and stock, especially stock, immediately perished. Without shepherds to take care of the sheep, the sheep wandered and were lost; eaten by the native dogs, killed by the natives and by some of the other colonists, very likely by his own workmen; but they were destroyed. His seeds perished on the beach; his houses were of no use; his wooden houses were there in frame, in pieces, but could not be put together, and were quite useless, and rotted on the beach. This was the case with the capitalists generally. The labourers, obtaining land very readily, and running about to fix upon locations for themselves, and to establish themselves independently, very soon separated themselves into isolated families, into what may be termed cottiers, with a very large extent of land, something like Irish cottiers, but having, instead of a very small piece of land, a large extent of land. Every one was separated, and very soon fell into the greatest distress. Falling into the greatest distress, they returned to their masters, and insisted upon the fulfilment of the agreements on which they had gone out; but then Mr Peel said, 'all my capital is gone; you have ruined me by deserting me, by breaking your engagements, and you now insist upon my observing the engagements when you yourselves have deprived me of the means of doing so.' They wanted to hang him, and he ran away to a distance, where he secreted himself for a time, till they were carried off to Van Diemen's Land, where they obtained food, and where, by the way, land was not obtainable by any means with so great facility as at the Swan River." (Report, &c. 53–4.)

That the semi-barbarous state of what are called new countries arises from the extreme facility of acquiring land, was first shown by Mr Wakefield, in a little work called a Letter from Sydney, published in 1829;[1] but his views had been communicated to government, we believe, before the departure of the Swan River settlers. The remedies which he proposed have since been substantially adopted, and wherever they have been applied, they have been attended with singular success.

Facility of acquisition being the evil, the remedy consisted in removing it by placing a price upon the waste lands in our colonies, and by stopping all alienation except in consideration of a price.

The first consequence of requiring a price for land is, that the labourer is compelled to labour a while for hire, until he shall have saved a sufficient sum to enable him to become a purchaser; and by devoting the proceeds, or a considerable portion of the proceeds, to defray the cost of removing people from the country in which people are abundant to the country in which they are deficient, a continual supply of labour is kept up. The supply being thus guaranteed, the colony becomes at once attractive to the capitalist; capital flows readily into such a country; and combination of labour, with perfect co-operation between the capitalist and labourer, being secured, production is facilitated and accelerated.

The mode of expending the labour-fund is another point of importance which requires explanation. The object is to relieve the population of the old country, and to increase to the utmost that of the new country, at the smallest possible cost. How is this to be done? Evidently by selecting the emigrants as to age and sex. By confining the expenditure of the emigration-fund derived from the land, to equal proportions of both sexes between certain ages, say eighteen and thirty-five, we give the greatest relief to the old country, and provide for the rapid peopling of the new. In other words, we remove from the country where people are in excess, to the country where they are deficient, the greatest germ of future increase at the smallest cost.

"By removing the selected class," says Mr Wakefield,

---

[1] Edited by R. Gouger, Cross, Holborn, 1829.

“ot only would you remove the greatest seeds of increase in the smallest number of people, but you would remove the greatest quantity of labour (using the term labour to express saleable muscular exertion) at the least cost. If there were a pressure upon the labour-market at home, by removing that class which was then commencing to work, and which had before it a long period of health and strength for labour, you would give the greatest relief to the labour-market with the least expenditure; and, in the next place, your object in the colony being the greatest possible labour at the least expense, by bringing to the colony a young man who had just arrived at his strength, but who has the prospect of a long life, you would give to the colony the greatest benefit at the least expenditure. Thirdly, there is in emigration the same sort of evil as there is in storms and floods. Emigration *per se* is an evil. It is the greatest evil to remove from the country of one's birth and one's affections. Now, by the proposed selection, since the greatest amount of emigration would really take place with the removal of the least number of people, you would obtain the maximum of good to be obtained by emigration, with the minimum of evil, whatever that evil may be. In the fourth place, there are great objections to any but young people; I will not say any but the narrow class to which I have adverted. Children suffer immensely in being removed. They suffer on board ship; they suffer from the confinement; and when they arrive in the colony, they are either neglected, or are a great encumbrance. Old people suffer much more from being removed from the scenes to which they are attached, and they are also less able to bear the fatigues which necessarily attend upon a long voyage. Lastly, almost every young couple no sooner marry in this country, or wherever they may be, than they look out for a new home. At the moment when they contemplate marriage, or at least when they are about to marry, they may be said to be on the move. You would catch them moving. You do not tear them from a place where they are fixed, but you would enable them to move to that place where their labour would be of the greatest possible value to them.”

Such are the principles of colonization, which have been successful wherever they have been applied, and the effects of which, in the colonization of New Zealand, we shall presently shew. They embrace a combination of the means which are requisite, not only for conveying masses, but for permanently establishing society in a new settlement. They perform their peculiar functions with the least possible disturbance of previous habits. They are the very opposite, the antagonist principles, as it were, of that planless practice which seems to have proceeded on the assumption, that to convey people to the new colony was the one thing needful. The example of Virginia has shewn, that the conveyance of mere masses alone to the fertile lands of new countries, is not sufficient to establish a colony. In Virginia, after twenty years of perseverance in colonizing, and after conveying 20,000 people, not above 2000 were to be found at the end of the period. There were people, there was wealth, there was intelligence, but all was ill directed. There was no system, and combined exertion was unknown. All our early efforts at colonization were disastrous. Under the new system, the causes of such disaster have been investigated and guarded against, with what success the following pages will shew.

Under the impulse of these principles, a complete revolution has taken place in the state of opinion on the subject of colonization. Persons to whom the bare idea of severing themselves from their native country was insuperably repugnant, now readily embrace a favourable opportunity of emigrating. Among the educated portion of the middle class, whose families are numerous, it is now not unusual to find some one or more of the sons seeking fortune in our distant possessions, and carrying to the antipodes those energetic habits which have made this country what she is.

Cœlum, non animum, mutant, qui trans mare currunt.

Women of refinement, too, no longer object to emigration, if circumstances favour the step; and New Zealand affords many instances of the emigration of whole families who have been accustomed to a species of society of which the older colonies were destitute, but which in our newer colonies they themselves help to form.

In the article Australasia, to which we have already referred, and in the life of the great navigator Cook, are stated the geographical position and extent of the New Zealand group, together with the circumstances of its discovery. As early as the year 1814, the northern part of the northern island began to be the resort of ships engaged in the whale-fishery, and men would occasionally desert from their ships and take up their residence among the natives. About the same time, some few of the natives of New Zealand occasionally made their appearance at Port Jackson, and being seen and conversed with by the Rev. Samuel Marsden, he conceived the idea of establishing a mission in the islands, which he accordingly visited for the purpose;[1] and although not immediately successful, the ultimate establishment of a mission was the result. Since that period, the Wesleyan Methodists and the Catholics have established missions, all of which have of late years extended their influence, bringing the natives into familiar intercourse with the Europeans, and generally promoting their civilization, in spite of certain questionable practices on the part of the church missionaries, which have brought them into some disrepute.

But the missionaries are not the only white men to whose influence the New Zealanders have been subjected. Up to the date of the commencement of the present movement, namely, 1839, the only colonizers of New Zealand were the very outcasts of an outcast population. Escaped convicts from the penal settlements; runaway sailors from whaling ships; needy adventurers, whose improvident habits and evil courses have made them men of no country; these, with a small admixture of worthy and energetic men, such as will find their way into all eligible fields, but who at that time formed too inconsiderable a minority to cure the vicious propensities and neutralize the evil passions of the majority, formed the bulk of the European population of New Zealand in 1839.

Dr Lang, principal of the Australian College at Sydney, who visited New Zealand during that year, thus describes the mass of the European population.[2] “Of the character of the European population, now permanently settled in New Zealand, it is scarcely necessary to inform your lordship. With a few honourable exceptions, it consists of the veriest refuse of civilized society; of runaway sailors, of runaway convicts, of convicts who have served out their term of bondage in one or other of the two penal colonies, of fraudulent debtors who have escaped from their creditors in Sydney or Hobart Town, and of needy adventurers from the two colonies, almost equally unprincipled. In conjunction with the whalers who occasionally visit the coast, the influence of these individuals on the natives is demoralizing in the extreme. Their usual articles of barter are either muskets and gunpowder, or tobacco and rum. Most of them live in open concubinage or adultery with native women; and the scenes of outrageous licentiousness and debauchery that are ever and anon occurring on their premises, are often sufficiently revolting to excite the reprobation and disgust of the natives themselves.

---

[1] Narrative of a Voyage to New Zealand in the Years 1814 and 1815, in company with the Rev. Samuel Marsden, by John Liddiard Nicholas, 1817.

[2] New Zealand in 1839; Four Letters to Lord Durham, by the Rev. Dr Lang. Smith and Elder, Cornhill.

"Of the character and practices of a considerable portion of the European population of New Zealand, the following may perhaps serve as a specimen. There is an individual at present at the Bay of Islands, who is known among the Europeans by the respectable *soubriquet* of the 'rat-catcher.' He had been a dealer in slop clothing, and a notorious gambler, in New South Wales; but having been obliged, when his affairs became desperate in Sydney, to leave that colony altogether, he embarked for the usual refuge of the destitute, New Zealand, and commenced his old practices as a general dealer and gambler at the Bay of Islands. On one occasion, when he had gambled away all his property at the Bay but a single box of spermaceti candles, he took a boat at Kororarika, and embarking with the box, rowed over to Paihia, one of the stations of the Church Missionary Society on the opposite shore, where he offered the candles to the missionaries at sixpence per lb., telling them he could procure them sixty pounds worth at the same price, from a vessel which had just arrived in the port, provided he could only advance the ready money for them. The missionaries of course advanced the money, which the 'rat-catcher' of course pocketed, and applied to his own purposes; thereby teaching the missionaries not to deal in future with disreputable persons, and especially not to attempt to purchase articles of property from such persons at one fourth of their market price."

Such was the character of the European population at the time when the present movement for the systematic colonization commenced, and indeed until it was in a manner neutralized by a large infusion of a sounder population. This movement had its origin in a conversation which took place in a committee-room of the House of Commons, on the occasion of the inquiry into the mode of disposing of the waste lands in the colonies in 1836. In the course of the evidence, New Zealand had been mentioned as one of the many eligible fields for colonization open to Great Britain. Mr Francis Baring's attention was thus excited; and the result was, that the New Zealand Association was formed, of which Mr Baring was chairman, for the express purpose of promoting the colonization of the islands.[1]

The New Zealand Association consisted of two classes of members; first, heads of families who intended to establish themselves in the proposed settlement; and, secondly, public men, who, on public grounds alone, were willing to undertake the responsible task of carrying the measure into operation. The sole aim of the association was to induce the legislature to apply to New Zealand the peculiar system of colonization which we have briefly described, and at the same time to make provision for guarding the natives from the evils to which they had been exposed by their intercourse with a lawless European population.

In 1837, this philanthropic body of men entered into communication with government on the subject, and at first there seemed some degree of willingness to promote the association's views; but at length a strange objection was raised, namely, that the association was not a company trading for profit. A charter was offered, on condition of its becoming such; but with this condition the association was not able to comply, having expressly excluded all purposes of private profit from its object. Having thus failed in its negotiation with the government, the association addressed itself to parliament. A bill was introduced "to establish a provisional government of British settlements of New Zealand;" but as ministers opposed the bill, it was of course lost. But although the association did not succeed in its object, it certainly did much to instruct the public on the subject. Through its exertions a committee was moved for in the House of Lords by the earl of Devon, and a large mass of valuable evidence was collected;[2] besides which, several publications issued from the press, either published by the association, or at their instance.[3] By these the public were undoubtedly prepared for the proceedings which have since taken place.

On the failure of its objects, the New Zealand Association became virtually dissolved; but some of its colonizing members attempted the formation of a joint-stock company, to meet the views of the government. After some difficulties and disappointments, the plan was attended with success. A company, with adequate capital, was established; and early in 1839 it had become possessed, by purchase from individuals and from the company of 1825, of some extensive tracts on the northern island. The proceedings of the New Zealand Company for the years 1839 and 1840 constitute a somewhat remarkable history; the history of British colonization from first to last does not furnish a more striking instance of vigorous action. Seldom has so much been effected in so short a period of time, and that too not merely without the sanction of the government, but in the face of opposition from it. That opposition, as we shall presently see, has been entirely obviated; and at this moment (August 1841) we find the New Zealand Company an efficient instrument for the colonization of New Zealand, under the superintendence of government.

Before the New Zealand Company made its plan of operations known to the public, it had purchased a fine bark of 400 tons, called the Tory. This vessel was fully equipped and ready for sea, when, on the 2d of May 1839, the company deemed itself in a situation to announce its plan of operations to the public. "The attention and business of the company," says the Prospectus, "will be confined to the purchase of tracts of land, the promotion of emigration to those tracts directly from the united kingdom, the laying out of settlements and towns in the most favourable situations, and the gradual resale of such lands according to the value bestowed upon them by emigration and settlement. It is also proposed, that to facilitate the transmission of capital between England and New Zealand, the company shall act as agents for that purpose only."

The Tory sailed from Plymouth on the first of May; and in a very able body of instructions given to Colonel Wakefield, the company's chief agent, the objects of the company are explicitly stated under three heads: 1st, the purchase of lands for the company, including the mode of dealing with the natives; 2d, the acquisition of general information respecting the country; and, 3d, preparations for the formation of settlements under the auspices of the company.

In these instructions, a strong leaning was exhibited towards Cook's Straits, as an eligible site for the first settlement, as being the great highway, so to speak, between the

---

[1] New Zealand seems at all times to have been considered an eligible field for the formation of a settlement. Benjamin Franklin proposed a plan for opening a civilizing commercial intercourse with New Zealand in 1771. In 1825, a commercial company was formed in London, under the auspices of the late earl of Durham. Two vessels were despatched to New Zealand, and land was acquired at Hokianga, Herd's Point, and at the estuary of the Thames; but the vessels returned without forming a settlement. From that period until 1839, the colonization has been confined to the species described in the above extracts.

[2] House of Commons Paper, 8th August 1838. No. 680.

[3] See especially the Colonization of New Zealand; being an Account of the principal Objects and Plans of the New Zealand Association. Parker, 1837.

Australian and eastern colonies and Great Britain. These predilections were shared by most of those who formed the first colony. Indeed as a commercial locality it is probably not surpassed in any onc of our Australian possessions. The Tory made an extremely short passage of ninety-six days; and Colonel Wakefield being thus in the field before any competitors, was enabled to fulfil the wishes of the company in every particular. He acquired for the company the whole of the territory on both shores of Cook's Straits, including Port Nicholson, one of the finest harbours in the world, where the principal settlement has since been successfully formed, and now numbers about four thousand people.

But the most gratifying feature in the company's instruction relates to the mode of dealing with the native tribes. Unhappily, the whole history of European colonization is but a continuous record of barbarity and injustice towards the aboriginal races. Civilization having often been found difficult, extermination has been openly practised. Even very recently, in New South Wales, a small body of the natives was hemmed in and shot down in cold blood by a few Europeans; and when the government took some steps to bring the monsters who perpetrated the act to justice, the press raised an outcry against punishing *men* for shooting *monkeys*; and an intimation was held out, that if this course were persevered in, it would be necessary to find some more secure method of getting rid of the "vermin;" and the mode recommended was, to dose wheaten cakes, of which the natives were very fond, with arsenic! This, reader, is no exaggeration; for in a letter from a brother-in-law of the present writer, a member of the English bar, dated Port Philip, December 3, the practice is mentioned as of common occurrence. "Some of the white people here treat the natives most shamefully. For the slightest offence they kill them, and drop their bodies into some creek; and some have been known to leave about what are called *dampers*, a species of bread baked in the bush, in which arsenic has been previously put, for the very purpose of destroying the blacks."

But the New Zealand Company inherited the higher views of the association of 1837. The elevation of the natives in every possible way is an object never lost sight of, and it is in their contracts with the natives respecting land that this object is especially conspicuous. In the first place, as regards the original purchase-money of the land, it was much more considerable than had been paid by any previous purchaser. This however was not the real consideration. The substantial advantage secured to the natives is, a reserve of one tenth of the whole of the lands purchased, which tenth must, as settlement proceeds, become of far greater value in consequence of colonization, and will confer much more substantial comfort on the native population, than the whole of the land could possibly do, so long as it remained in their own possession. Of the 1100 town acres, with the 110,000 country acres, which constitute the first colony, one tenth was so reserved. The company sold these lands at 20s. per acre, consequently the native reserves were worth at the time L.11,110; but such has been their rise since, that they are worth upwards of L.35,000 in the London market; a value which will place the natives of Port Nicholson in a most advantageous position in relation to the colonists.

The plan is indeed admirably suited to promote the civilization of the natives. They do not require an enormous breadth of land, for they are, and always have been, cultivators, not hunters like the American Indians. America abounds with animals which either serve as food for the natives, or furnish them with the means of procuring by barter such objects as are suited to their wants. New Zealand, on the contrary, has no aboriginal animals. This may have made them cannibals; but it has also of necessity made them cultivators, and has thus advanced them one step in civilization. It has rendered them prone to labour, and they now adopt with great readiness the improvements of civilized life. Among hunters, such as the American Indians are at this day, no circumstance could give value to a small quantity of land, so as to make it provide for the subsistence of the natives; but with a race of cultivators, a great breadth of land is valueless. They cannot use much land; and they may therefore be deemed well provided for, in proportion as they are taught to use a comparatively small quantity of land with effect.

All modern accounts which deserve credit agree in describing the habits of the New Zealanders as exceedingly favourable to their elevation. They learn the use of mechanics' tools with great readiness, and even become good ship-carpenters. Many of the first settlers at Port Nicholson found the houses built by the natives, called *warrees*, much more comfortable than any others. They become excellent boatmen and sailors; and there are instances of small vessels built and navigated by New Zealanders. Dr Lang states, that Toki, a New Zealander, was the best helmsman on board the ship in which he made a passage; and in the evidence before the Lords' Committee, many instances are given of natives capable of taking charge of a ship as master, were it not that, as *foreigners*, they were incapacitated by law from so doing.[1]

The views of the company touching the aborigines have up to this time been admirably seconded in the colony, not merely by their own officers, but by the settlers at large. In the very first instance, by the uniform fairness of his dealings, and especially by the temper displayed in all his negotiations, Colonel Wakefield succeeded in gaining their confidence, and in establishing the most friendly relations; and the settlers, on their arrival, found them predisposed to receive them with friendship, and perform for them such services as they immediately needed. In the various letters from the first settlers which have been published[2] from time to time during the last twelvemonths, both the capacity and disposition of the natives are well spoken of, and it is quite evident that mutual feelings of kindness and good will have grown up between the settlers and the natives.

Soon after the departure of the Tory, the company made preparations for disposing of a limited portion of their lands already acquired, or hereafter to be acquired, for the purpose of forming the first colony. The quantity assigned for this purpose was eleven hundred acres for the town, and one hundred and ten thousand acres to form the rural sections, of one hundred acres each. These lands were divided into eleven hundred sections, each section to comprise one hundred rural acres and one town acre. Deducting the reserved land for the aborigines, the remainder was offered for sale at L.1 per acre, or L.101 per section. On paying down this sum, the purchaser received a land-order on the company's local officer, entitling the holder to select his section according to priority of choice, afterwards determined by lot at the company's offices.

The quantity of land thus disposed of in the first instance, was taken in a few weeks. The total sum realized, after deducting the native reserves, was L.99,990. Of this sum 75 per cent. or L.74,992. 10s. was set apart to form the emigration fund for the purpose of defraying the cost of conveying emigrants to the colony, and so impart value to the lands already sold. By the conditions of sale, the purchasers of land-orders were entitled to claim 75 of their purchase-money, either in the shape of free passages for themselves and families, or for their servants and labourers; and where no claim was made, the benefit was equally conferred on the landowner, as the whole of the emigration fund would be devoted to the conveyance of labour to the colony.

[1] Information relative to New Zealand, by John Ward, Esq. Parker, 1840. The New Zealanders (Library of Entertaining Knowledge). Knight, 1830.

[2] A great number of such letters has appeared in the New Zealand Journal, a paper published in London once a fortnight, and devoted to the colonization of New Zealand.

It should be observed, that the buyers of these lands knew not at the time where the first colony would be located. They knew that the company had some land to fall back upon, but the general impression was, that the first colony would be established on the lands about to be acquired, and Port Nicholson was looked to by some of the principal colonists as likely to form an eligible site. This has since been accomplished. Port Nicholson was found to be in every way fitted to become a great commercial emporium, and the satisfaction which the settlers express with the selection is universal.

Immediately after the realization of the land-fund in July, active preparations were made for the departure of the first colony. A surveyor, with what was then deemed an adequate staff, but which subsequent experience has shewn to have been too small, was despatched in the Cuba. She sailed two months in advance of the settlers, but, unfortunately, she made a long passage, and at the time the first emigrant ship reached Port Nicholson, not a step had been taken towards the laying out of the town. This inconvenience was however obviated by Colonel Wakefield's arrangements; and by assigning small allotments of land to the settlers, on which they might erect their tents and houses, discontent was entirely avoided.

The ships chartered by the company to take out the first colony were five in number, namely, the Adelaide, the Aurora, the Oriental, the Duke of Roxburghe, and the Bengal Merchant. It afterwards became necessary to take up the Glenbervie to take out stores, and the Bolton to take about 232 passengers, who had been disappointed in obtaining passages by the first ships. The first sailed on the first of October, and the last in the middle of November, and, with the Coromandel, a private ship, conveyed 1125 persons to the colony.

The distinguishing feature of this first colony is its completeness. No colony was ever established under more favourable prospects. The labouring emigrants, the bone and muscle of the colony, formed the finest body of people we ever saw congregated together for such a purpose, albeit our experience in such matters is not small. Selection was observed not merely to the extent which the principles require, but also as to the moral and physical qualifications of the people. They were for the most part in the prime of life, in full health, and of approved moral character; and it was impossible to look upon them without a conviction that they were the very people to carve fortune out of the wilderness.

Among the wealthier classes were several persons of birth, education, and refinement, who, in planting a new colony, will not be content with a mere rude abundance, nor with their new home, unless it bear distinct marks of a high degree of civilization. They went out impressed with the value of a system of which they themselves form a part; they believe that system to be efficient for the creation of a society complete in all its parts; and believing so, all their energies will be directed to the verification of the principles to which they are attached. The varieties of form in which the capital was conveyed to the colony will show how efficient that capital is likely to become as a means of contributing to the satisfaction of the wants of the colonists. Houses and other buildings, in frames, ready to be put up like a bedstead in the course of a day[1] or two; mill-machinery of all kinds, both for sawing and grinding; steam-engines; agricultural implements of the most improved kind; mechanics' tools, especially all that might be necessary to the builder, were among the articles carried out. But this was not all. In addition to that in which the idea of immediate profit was predominant, the moral and intellectual wants of the people have not been forgotten. Even before the departure of the first colony, a literary and scientific institution was established, and the germ of a library formed, to which the archbishop of Dublin, the Rev. Dr Hinds, and several other friends of the colony, contributed. The press also was not forgotten. The first number of a newspaper, called the *New Zealand Gazette*, was published in London in August 1839, with the intention of publishing the second and succeeding numbers in the colony. The types and presses, the editor, foreman, and compositors, went out in the Adelaide. She reached Port Nicholson on the 7th of March, and on the 18th of April the second number was printed at Port Nicholson. We have now before us a file to the 5th of December, and its contents bear remarkable testimony to the completeness of the system, and the extraordinary rapidity with which the settlement has increased. A newspaper "exclusively devoted to New Zealand," is also published in London. It is called the New Zealand Journal; it appears once a fortnight, and has a considerable and steadily increasing sale; a proof that what has very aptly been called the "New Zealand public" in this country is also large and increasing.

We have already seen that neither the New Zealand Association of 1837, nor the New Zealand Company of 1839, could win the sympathy or even the countenance of the government. By the energetic operations of the latter body, however, the government were forced into action; and just as the first colony was ready to start, Captain Hobson of the navy was sent to New Zealand for the purpose of ultimately erecting it into a British colony. Unfortunately, New Zealand, or rather the northern portion of the northern island, had been treated in 1831 as a sovereign independent state, and Captain Hobson was instructed to begin by calling himself *consul*. He was then to obtain a cession of the sovereignty from the chiefs, and declare so much of the country as should be ceded to him, and also such part thereof as should be in possession of British subjects, a dependency of New South Wales. Of this portion he was to cease to call himself consul, and was to become lieutenant-governor under Sir George Gipps, the governor of New South Wales. In other words, New Zealand was treated as a foreign country, over which her majesty could have no authority, until it should be obtained by formal cession, from the date of which, sovereignty with all its consequences would commence.

From this course of policy much difficulty has since arisen, and more will yet arise. It is a well-understood principle of international law, that discovery and occupation give to the discovering nation a right of sovereignty *as against all civilized powers*. The relations which the discovering country may establish with the native tribes do not in any way affect this right of sovereignty. The

---

[1] The house designed for the printing of the first newspaper, the *New Zealand Gazette*, was put up by the proprietor and a couple of men in two days. It was made by Manning of Holborn, and was taken out in frame.

Americans, for instance, recognise a certain modified sovereignty as continuing in the Cherokees and other aboriginal tribes, but they nevertheless assert the sovereignty of the Union as against all European nations. Of our original sovereignty over New Zealand no one ever doubted, until it was lately repudiated or renounced by the colonial department. Acts of sovereignty had frequently been exercised. Magistrates had been appointed; criminals had many years since been arrested, sent to Sydney, tried, and punished; and yet it was determined that Captain Hobson should take a new lease of sovereignty, dating from a first cession or successive cessions from the natives.

One of the consequences of this was, that New Zealand, which had all along been respected by foreign powers, was immediately thrown open to colonization by any European power. France at once took the hint, and sent out the Comte de Paris transport with about sixty settlers, to found a French colony there. This expedition was only twenty days too late to take possession of the southern island in the name of France. Twenty days before, Captain Hobson had declared the queen's sovereignty over both islands, otherwise we must either have submitted to have a French colony on the southern island, or have reverted to our ancient seisin, declared a species of retrospective sovereignty, and stultified the recent proceedings of the government in that behalf. And in point of fact this has been done. Captain Hobson at first pursued the plan of cession. The chiefs of a small portion of the northern island north of the estuary of the Thames were assembled to barter sovereignty for a blanket. Captain Hobson thereafter proclaimed the queen's authority. With the proclamation of sovereignty a second proclamation was issued, appointing a commission to inquire into the titles to land, to confirm such as might have been obtained by fair means, and to disallow such as might have been obtained for fraudulent or inadequate consideration, or where the extent of territory claimed was unreasonably large. This second proclamation has since been carried into effect by an act of the council of New South Wales. Now this act, together with the second proclamation respecting titles, is utterly inconsistent with the first proclamation, which makes her majesty's sovereignty commence with the date of the cession in January 1840. Proclamation No. 1 denies her majesty any jurisdiction previously to 1840. Proclamation No. 2 asserts jurisdiction for an indefinite period before that date. In other words, our "ancient seisin" is reverted to her majesty, to use the language of our ancient legal writers, is "in of her old estate;" and the whole ceremony of the formal cession is treated as a solemn farce. Indeed Captain Hobson himself found it necessary to cut the gordian knot, and renounce the scheme of obtaining the sovereignty bit by bit by means of cession; for in May he issued a proclamation, declaring her majesty's sovereignty over both islands, and so anticipated the French expedition by twenty days.

Without reverting to our ancient sovereignty, so as to give her majesty jurisdiction antecedently to January 1840, not merely could no title be questioned previously to that date, but many crimes must go unpunished, if they were not crimes according to the customs of New Zealand. What we call murder was undoubtedly sanctioned by the "sovereign chiefs of New Zealand" in 1839; and a mere tyro in pleading would have no difficulty in framing a plea in abatement of the indictment, provided the doctrine of the proclamation was to be maintained.

But to return to the proceedings in this country. After the departure of the first colony in the autumn of 1839, no further emigration took place for some time. In the month of February 1840, two vessels, the Brougham and the Platina, were despatched, the former with provisions for the colony, and the latter with one of Manning's houses for Captain Hobson; but in the state of uncertainty which then existed, the company did not deem it expedient to promote emigration. Nothing had been heard of the Tory, all was doubt respecting Captain Hobson's proceedings, the government continued hostile, or at least withheld its sanction, and rumours of French rivalry, greatly exaggerated and over-estimated, conspired with the unsatisfactory state of our relations with France to render delay prudent. The friends of New Zealand felt that any one favourable piece of intelligence would renew public interest in the question, and create a spirit which would dash aside all other difficulties; but when all was uncertainty and doubt, it would be unwise to attempt to carry public opinion by storm. This state of uncertainty did not long continue. Early in March, news of the arrival of the Tory reached this country. The expedition had been in every way successful, and Colonel Wakefield's despatch, published in the New Zealand Journal of the 10th of March, shewed that all the expectations of the company and the public would be abundantly fulfilled.

The very favourable accounts which were received from New Zealand at the very moment that the rumours were current respecting the designs of the French in that quarter, aroused the great commercial interests of the city. On the 15th of April, a numerous and very respectable meeting took place in Guildhall. It had been convened by a requisition signed by one hundred and fourteen "of the higher classes of bankers, merchants, shipowners," as they were described by the Times newspaper, and it was attended by a numerous assemblage of persons, by some of whom all the great interests in the city were represented. As if in anticipation of this meeting, a series of papers was laid on the table of the House of Commons the evening before the meeting, entitled "Correspondence with the Secretary of State relative to New Zealand," where, in the shape of a "memorandum," dated 18th March, "the pretensions made in behalf of her majesty" respecting the sovereignty of New Zealand were "repelled," and New Zealand declared "a substantive and independent state." A meeting of this character was not to be put down, however, by a mere declaration of the opinion, for it really amounted to no more, of one of the under secretaries of state. It merely seemed to stimulate both speakers and listeners, and a petition to her majesty and both houses of parliament, praying that the subject might be taken into immediate consideration, "to preserve these valuable islands to her majesty's dominions," was numerously signed in the hall. The petition was afterwards brought before the house by Lord Eliot, who, with great industry, had completely mastered the subject. A committee was appointed, and a body of evidence collected, which completely showed that the government could no longer lag behind the active colonizers of New Zealand.

From the period of Lord Eliot's successful motion, the colonization of New Zealand, and every thing connected with it, have prospered in every way. From Lord John Russell's speech, although in the first place he opposed Lord Eliot, it was evident that he was actuated by no vindictive feeling, and the friends of New Zealand were soon made aware that the fostering aid of government would no longer be denied them. Immediately after the city meeting, the arrival of a second favourable despatch from Colonel Wakefield justified the company in recommencing emigration. The Martha Ridgway was taken up, and sailed on the 9th of July, taking out the report of the debate on Lord Eliot's motion, since which time a shipload of emigrants, selected on the principle we have described, has sailed every month; so that up to the end of June 1841, 3469 emigrants had been sent out by the company alone, besides about four hundred by the Plymouth Company, and perhaps about three hundred others independently of either company.[1]

The relations between the company and the government for some time previous to the close of the year 1840 had been on a most satisfactory footing. Though the state of *quasi* hostility which had existed might have created feelings of acrimony, Lord John Russell, in the negotiations which took place after the committee of July, displayed great magnanimity; and towards the end of October the New Zealand Company were enabled to announce that the differences which had existed between the government and the company had been finally adjusted. On the 5th of December the terms were published, by which it appeared that New Zealand was to cease to be a dependency of New South Wales, as Captain Hobson, according to his instructions, had declared it, but was to become an independent colony. A charter was to be granted to the company, which was to cede its land to the government, receiving, in return for its outlay, an ample consideration in land. These arrangements have since been carried into effect. The charter has been granted, and the company has become a most efficient instrument in the hands of government for the colonization of the country.

Great discontent prevailed, both at Port Nicholson and the Bay of Islands, respecting their state of dependency on New South Wales, and the numerous inconveniences to which that relation gave birth. To quiet the minds of the colonists without delay, a fast-sailing vessel was taken up to carry the despatches containing the terms of the final arrangement, which, it was calculated, would reach Port Nicholson by the end of March.

From this time forward, therefore, nothing will be wanting to the rapid colonization of the islands. All the settlers' letters agree in describing the country as rich and fertile, and the climate as salubrious. The country is abundantly watered, and the droughts which prevail in Australia are utterly unknown. The only complaint is the scarcity of flat clear land. But the wooded character of the land is no evil. In America it is deemed the test of a good soil, and no man will take land which does not require the labour and expense of clearing. The opinion in favour of clear land is an Australian prejudice, justifiable if confined to pasture land, but not so if extended to land destined for tillage. New Zealand, in fact, is destined to become a wheat country, the granary of the Australian colonies. As a sheep country, it must yield to the dry and arid wastes of Australia. The vine and the olive flourish already almost without the aid of man; and there is no doubt that New Zealand is adapted to all the productions of southern Europe.

The natives, instead of being an encumbrance, are an acquisition. It is gratifying to read in the settlers' letters the affectionate terms in which their intercourse is carried on. Mutual kindness to each other's children is one of the most striking features. We have already stated the aptness of the natives to imitate the arts and contrivances of Europeans. In this respect they are improving rapidly. Their physical superiority is greatly in their favour. The women are comely, and some beautiful; they are gentle in their manners, and are said to make good and attached wives. Several are united to Europeans; and there seems no impediment to more extensive amalgamation, which the principles of the company, now adopted by the government, by investing the natives with property, will greatly encourage.

The geographical character of both the islands seems to point out the peculiar mode of settling which the company have put in practice. The islands being long and narrow, present an immense line of sea-coast in proportion to the extent of surface. This line of coast is broken into numerous splendid harbours, on many of which Europeans had established themselves; but as far as our present information goes, there are no large rivers extensively navigable for large ships, though many of them are well adapted for internal navigation. The best mode of colonization therefore is to establish distinct settlements on all to the principal harbours of both islands.

Port Nicholson, the site of the first colony, is one of the finest harbours in the world. Its situation will make Wellington the great commercial metropolis, not merely of New Zealand, but of the whole of our Australasian possessions. The Bay of Islands, another admirable commercial station, is already settled to a considerable extent. A branch of the New Zealand Company, called the Plymouth Company of New Zealand, has sent out a surveying expedition, and a body of settlers to establish a colony on some eligible spot, to be determined by their agent, in conjunction with Colonel Wakefield. An eligible site for the New Plymouth settlement has been found on the banks of the Waitera river, at Teranaki, twelve miles from the Sugar-Loaf Islands. The town is to be called Port Eliot, after an estate of Lord St Germains, and in honour of Lord Eliot, to whose exertions the New Zealand colonists are so much indebted.

Acting on this plan, the company are now about to form a second settlement (or reckoning the New Plymouth settlement as one, a third), to be called Nelson. The preliminary expedition, consisting of two vessels, the Whitby and Will Watch, and having on board the company's agent, Captain Wakefield, R. N., the agent for the New Plymouth settlement, Captain Liardet, R. N., who was Commodore Napier's commander on board the Powerful at Acre, together with a surveying staff, consisting of a chief surveyor, six assistants, twelve improvers or apprentices, and eighty men, sailed on the 27th April; and a large body of colonists are now (August) preparing to depart.

The extent of land allotted for the second colony is two hundred and one thousand acres, divided into one thousand allotments of one hundred and fifty rural acres, fifty suburban acres, and one town acre. The price of each allotment is L.300, so that the total sum placed at the disposal of the company will be L.300,000. Out of the thousand allotments, only about three hundred remained to be disposed of at the end of June. The L.300,000 will be thus distributed: L.150,000 for the emigration of young couples to this particular settlement; L.50,000 to defray the cost of surveys, establishments, &c., any surplus to go to the next head; L.50,000 for public purposes, as, for instance, the encouragement of steam navigation (L.20,000), the establishment of a college (L.15,000), religious endowments (L.15,000); L.50,000 to the company for its expenses, and profit on the use of its capital. The body of the colonists will sail in September.

Emigration to Port Nicholson will still be continued. The company has just increased its capital from L.100,000 to L.200,000, in compliance with a condition in the charter, and emigrants will be conveyed to the first settlement in anticipation of the land-sales which will take place in the colony so soon as the "final arrangement" already alluded to shall have been made known in the colony.

One subject of great importance to New Zealand, indeed to all the Australian colonies, remains to be mentioned,

---

[1] The following is an estimate of the white population of New Zealand at this time, including the emigration from this country during 1840, but exclusive of that of the present year.

Wellington and Port Nicholson	3177

Zeitz.

amely, communication with those colonies by way of the sthmus of Panama and the Pacific Ocean.

The West India Steam Navigation Company have a contract to carry the mails by steam for a certain number of ears. The steam-ships for this purpose are now building t Northfleet near Gravesend, and we believe will commence unning in the autumn of the present year (1841). From amaica to Chagrès or Puerto Bello, on the Atlantic side of he isthmus of Panama, is only 550 miles, which will also e accomplished by steam by the above-named company. t is now proved beyond all doubt that the isthmus offers o difficulty, in the way of a railroad or a ship-canal, which oney, and even a moderate sum of money, will not accomlish. See PANAMA.

From Panama, on the Pacific side of the isthmus of that ame, steam is already established to Lima, and occasionally to Valparaiso. All, then, that will remain to be done after the vessels of the West India Steam Navigation Company shall have commenced running, will be to establish some regular communication between the western coast of South America and New Zealand. This can be done monthly with four fast-sailing vessels; and it is understood that the company is prepared to give a remunerating charter to any builder or merchant who will undertake to provide the ships. It should be observed, that there is every prospect of a remunerating trade for such vessels, as, even at this early stage of the settlement, two vessels from Valparaiso have arrived at Port Nicholson, and at the date of the last advices one was preparing to sail for that port. Callao in Peru is mentioned in the Report of the Directors of the New Zealand Company as a port favourable for the establishment of such communication.

The time at present occupied by the voyage to New Zealand is one hundred and twenty days. By the way of the isthmus it may be calculated as follows:

To Jamaica	21 days.
Thence to Puerto Bello	3
Across the isthmus	3
From Panama to Valparaiso	10
Thence to New Zealand	43
	80

It only remains to mention that Captain Hobson has fixed upon the harbour of Waitemata, in the estuary of the Thames, as the seat of his government. He has made preparations for the establishment of a town, to be called Auckland, which is in latitude 30° 51′ 36″ south, and longitude 174° 43′ east. At present it only contains about 200 inhabitants; and although under the fostering influence of the government it will doubtless increase, it must ever remain insignificant compared with the commercial capital, Wellington. To that and the other settlements separate municipalities will be given. Judicial and other officers have been appointed and sent out; so that before the end of the present year the government of New Zealand will be completely organized, and the country will be in a fair way to become one of the most prosperous, as it is now one of the most attractive, of our colonial possessions.

For the use of such of our readers as may wish for full information on the subject, the following is a chronological list of works relating to New Zealand, which, with the exception of a few controversial pamphlets, is believed to be complete.

1770–80. Cook's second and third Voyages.
1807. Some Account of New Zealand, by John Savage, Esq. Surgeon.
1817. Narrative of a Voyage to New Zealand, by J. Liddiard Nicholas, Esq., 2 vols.
1824. Journal of a ten Months' Residence in New Zealand, by R. A. Cruise, Esq., Major in the 84th Regiment of Foot.
1830. The New Zealanders (Library of Entertaining Knowledge).
1832. Authentic Information relative to New South Wales and New Zealand, by James Busby, Esq.
1832. A Narrative of a nine Months' Residence in New Zealand in 1827, by Augustus Earle, Draftsman to H. M. surveying ship Beagle.
1835. An Account of New Zealand, by the Rev. W. Yate, Missionary of the Church Missionary Society.
1836. Polynesian Researches, by the Rev. William Ellis.
1837. The British Colonization of New Zealand; published for the New Zealand Association.
1838. The latest Official Documents relating to New Zealand, with introductory Observations, by the Rev. Samuel Hinds, D. D.
1838. Report of the Lords' Committee on the present State of the Islands of New Zealand.
1838. Journal of a Residence in New Zealand, by J. S. Polack, 2 vols.
1839. New Zealand in 1839, or four Letters to the Earl of Durham, by John Dunmore Lang, D. D.
1840. Information relative to New Zealand, compiled for the use of Colonists, by John Ward, Esq.
1840. Supplementary Information, published by Parker, West Strand.
1840. An earnest Address to New Zealand Colonists, with reference to their Intercourse with the Native Inhabitants, by the Rev. Montague Hawtrey.
1840. Manners and Customs of the New Zealanders, by J. S. Polack, 2 vols.
1840. Correspondence relative to New Zealand. Par. Paper.
1840. Report on New Zealand, Lord Eliot's Committee. Par. Paper, No. 582.
1840–41. The New Zealand Journal, published every other Saturday. London.
1841. Parliamentary Paper, No. 311, 11th May; with an excellent Map. (D. L.)

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law and the honour of religion.

ZEBID, a city of Arabia, once the capital of Yemen; but its port having fallen into a state of decay, the principal city of the province is now Mocha. The old mosques and minarets still give to the place a magnificent appearance from a distance, and it is still distinguished by an academy, much resorted to by the youth of Yemen. But it is gradually falling into ruins, so that it has become an employment for the people to carry off the stones, which are sold to be elsewhere applied to the purposes of building. Zebid is 52 miles north of Mocha.

ZEBU, one of the Philippine Islands, situated about the 123d and 124th degrees of east longitude. It is 108 miles in length by 24 in breadth. It is remarkable as the place where Magellan fell in a skirmish with the natives in 1521.

ZEITZ, a city of Prussia, the capital of a circle of the same name, in the province of Saxony and government of Merseburg. It stands on a height above the river Alster, over which is a stone bridge. It is surrounded with walls, has three good market-places, a palace in which is a library of 12,000 volumes, four churches, a free grammar-school, two hospitals, and 8929 inhabitants in 1834. Zeitz is a place of considerable industry, applied to fabrics of woollen goods, calico-printing, brewing, and distilling. It is celebrated for the productions of its gardens and nurseries.

ZELEH, a town of Asiatic Turkey, in the government of Sivas, twenty-one miles west-south-west of Tocat.

ZELENIN, a small island in the Frozen Ocean, near the south-west coast of Nova Zembla. Long. 56. 24. E. Lat. 70. 50. N.

ZELENOIKOLOK, as fortress of Asiatic Russia, in the government of the Caucasus, on the Oural.

ZELEZENSKAIA, a fortress of Asiatic Russia, in the government of Kolivan, on the eastern side of the Irtysch.

ZELLE, a city of the kingdom of Hanover, in the province of Lüneburg, in Germany. It stands on the river Aller, at the point where the Fuse falls into that stream. It is surrounded with walls and ditches, is the seat of the supreme courts of law, and of the Lutheran superintendent general. It has a gymnasium, and several other establishments for education, and contains three Lutheran, one reformed, and one catholic church, 1460 houses, and 10,300 inhabitants, including those of the suburb. There are various manufactures, but mostly on a small scale; but a considerable trade arises from the city being the great thoroughfare for the goods conveyed by waggons between Hamburg, Bremen, and the middle and south of Germany. Adjoining to the city is the ancient palace of the dukes of Zelle. It is not in very good condition, none of the royal family having lived in it since the death of the unfortunate queen of Denmark, Caroline Matilda, who held her court in it till her death. Long. 9. 57. 4. E. Lat. 52. 37. 3. N.

ZEMANIAH, a town of Hindustan, in the province of Allahabad and district of Benares, situated a short distance from Ghazipore, on the Ganges.

ZEMBLA, Nova, a large island in the Arctic Ocean, belonging to Russia, lying between 55° and 77° E. long. and 70° and 78° N. lat. It is about 700 miles in length, with an average breadth of seventy-five miles. No part of this dreary region has any permanent inhabitants, but some districts on the west and south coasts are occasionally visited by fishermen and hunters. The island is intersected in two places by narrow straits, and a prolongation of the Uralian Mountains runs along it from south to north. It chiefly consists of a marshy moss-clad plain, the undisturbed possession of bears, white foxes, and other wild beasts.

ZEMINDAR, in its original meaning, signifies a great landholder of Bengal; but it is now more strictly applicable to those who have their title constituted or confirmed by a patent or charter from government, by which they hold their lands or zemindaries upon certain conditions. It appears from history, that in times prior to the irruption of the Mahommedans, the rajahs who held their residence at Delhi, and possessed the sovereignty of Hindustan, deputed officers to collect their revenues. The word *zemindar* is Persian, and that language could have had no currency in the countries of India, until it was introduced by the people of Persia. When the emperor Shehab-ul-Dien Ghory conquered the empire of Hindustan at the end of the 12th century, he left Sultan Cutub-ul-Dien to be his viceroy at Delhi, and administer the government of Hindustan. From that time the customs and practices of the Mahommedans began gradually to be established in India: their armies were sent into the countries of the reduced rajahs, under the command of omrahs, in order to preserve the conquest; and lands were allotted to them to defray the expense. From hence arose the system of jaghiredary in Hindustan. But when these omrah jaghiredars had established their own strength, several of them rebelled against the imperial authority, and aspired to the crown. Thus circumstanced, the emperors, in order to obviate these mischiefs, thought it would be more politic to commit the management of the country to the native Hindus, who had most distinguished themselves by the readiness and constancy of their obedience to the sovereign power.

In pursuance of this plan, districts were allotted to numbers of them under a reasonable revenue (Jummah Monâsib), which they were required to pay in money to the governors of the provinces, deputed from the emperor; and in case any one of the omrahs or provincial governors should swerve from his allegiance, the zemindars of that country were to exert themselves in such a manner as should check rebellion, and restore good government. For this purpose, grants of zemindary were severally conferred upon such of the Hindus as were obedient, describing their apportionment of the country; and every person who had received a grant under the authority of the crown, was thereby fully invested with the functions of zemindar.

The functions of a zemindar are, 1st, the preservation and defence of their respective boundaries from traitors and insurgents; 2dly, the tranquillity of the subjects, the abundance of cultivators, and increase of his revenue; 3dly, the punishment of thieves and robbers, the prevention of crimes, and the destruction of highwaymen. The accomplishment of these objects is considered in the royal grant as the discharge of office to the sovereign; and on that account the word *office* (khidmut) is employed in the Dewanny Sunnud for a zemindary. See Hindustan.

ZEMPLIN, a circle of Hungary, in the province of the Hither Theiss. It is bounded on the north by Gallicia; on the east by Unghvar and Garasch; on the west by Borsod, Abouigvar, and Saroch; and on the south by Szabolts. It extends over 2244 square miles, and contains twenty-four market-towns and 428 villages, with 27,199 houses, and 233,604 inhabitants, of whom four fifths are catholics, and the remainder of the protestant church. The northern part includes a portion of the Carpathian Mountains, and is sterile; but in the south the soil is good, yielding, among other products, some of the best wine. The capital is the town of the same name, on the river Bodrog. It has an ancient castle, a catholic and a protestant church, and 2800 inhabitants, whose chief trade is in wine. Long. 21. 43. E. Lat. 48. 25. N.

ZEND, or Zendavesta, a book ascribed to Zoroaster, and containing his pretended revelations, which the ancient Magians and modern Parsees, called also *Guurs*, observe and reverence in the same manner as the Christians do the Bible and the Mahommedans the Koran, making it the sole rule both of their faith and manners. The word, it is said, originally signified any instrument for kindling fire, and it is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of those who read it.

The Zend contains a reformed system of Magianism, teaching that there is a Supreme Being, eternal, self-existent, and independent, who created both light and darkness, out of which he made all other things; that these are in a state of conflict, which will continue till the end of the world; that then there shall be a general resurrection and judgment, and that just retribution shall be rendered unto men according to their works; that the angel of darkness with his followers shall be consigned to a place of everlasting darkness and punishment, and the angel of light with his disciples introduced into a state of everlasting light and happiness; after which light and darkness shall no more interfere with each other. The Zend also enjoins the constant maintenance of sacred fires and fire-temples for religious worship; the distinction of clean and unclean beasts; the payment of tithes to priests, which are to be of one family or tribe; a multitude of washings and purifications, resembling those of the Jewish law; and a variety of rules and exhortations for the exercise of benevolence and charity.

In this book there are many passages evidently taken out of the Scriptures of the Old Testament, particularly out of the Psalms of David. The author represents Adam and Eve as the first parents of all mankind, gives in substance the same account of the creation and deluge with Moses, differing indeed with regard to the former, by converting

e si days of the Mosaic account into six times, compre-
ndin in the whole 365 days; and speaks also of Abra-
m, Joseph, Moses, and Solomon. Dr Baumgarten more-
er asserts, that this work contains doctrines, opinions,
d facts, actually borrowed from the Jews, Christians, and
ahommedans; whence, and from other circumstances, he
ncludes that both the history and writings of this pro-
et were probably invented in the later ages, when the fire-
rshippers under the Mahommedan government thought
to vindicate their religion from the suspicion of idolatry.
At whatever period the Zend may have been written, we
e assured by Dr Hyde that it is in the pure old Persian
ngue, and in the character called *Peplavi*. Some parts
it contain the original text, and others Zoroaster's se-
nd thoughts subjoined, for explaining more fully his doc-
ne. These were occasioned by the opposition of adver-
ies, and unforeseen circumstances which occurred dur-
g th progress of the imposture. About 300 years ago,
hen he old Persian language had become antiquated and
tle understood, one of the destours or high priests among
e Pa sees composed the *Sadda*, which is a compendium,
the vulgar or modern Persic tongue, of those parts of the
nd hat relate to religion, or a kind of code of canons and
eceps, drawn from the theological writings of Zoroaster,
vin as an authoritative rule of faith and practice for his
lowers. This Sadda is written in a low kind of Persic
rse and, as Dr Hyde informs us, it is *bonorum et malorum*
rrag, having many good and pious things, and others
ry perstitious and trifling.

ZE DEROOD, a river of Persia, which rises in a moun-
n to the east of Ispahan, and passes through that city,
here three handsome bridges are built across it.

ZE GHI, a river of Armenia, which falls into the Aras,
n mes south of Erivan.

ZE ITH, in *Astronomy*, the vertical point, or a point
the heavens directly over our heads.

ZE O Eleates, an eminent Grecian philosopher, was
rn Elea about 504 years before Christ. He was a zea-
us fiend of civil liberty, and is celebrated for his coura-
ous nd successful opposition to tyrants; but the incon-
ten of the stories related by different writers concern-
g hi in a great measure destroys their credit. He chose
re e in his small native city of Elea rather than at
the, because it afforded freer scope to his independent
d nerous spirit, which could not easily submit to the
straits of authority. It is related that he vindicated the
rm with which he resented reproach, by saying, "If I
re different to censure, I should also be indifferent to
ise." The invention of the dialectic art has been im-
ope ascribed to Zeno; but there can be no doubt that
s pilosopher, and other metaphysical disputants of the
eati sect, employed much ingenuity and subtilty in ex-
biti examples of most of the logical arts, which were
erwrds reduced to rule by Aristotle and others.
Acording to Aristotle, he taught that nothing can be
oduced either from that which is similar or dissimilar;
at tere is only one being, God; who is eternal, homo-
neo, and spherical, neither finite nor infinite, neither
esent nor moveable; that there are many worlds; that
re in nature no vacuum; that all bodies are composed
fou elements, heat and moisture, cold and dryness; and
at te body of man is from the earth, and his soul an
ual mixture of these four elements. He argued with
eat ubtilty against the possibility of motion. If Se-
ca's account of this philosopher deserves credit, he
achd the highest point of scepticism, and denied the ex-
enc of external objects. The truth is, that after all that
s ben advanced by different writers, it is impossible to
terme whether Zeno understood the term *one* meta-
ysically, logically, or physically; or whether he admitted
dered a nature properly divine.

Zeno.

Zeno, the founder of the sect of the Stoics, was born about 300 years before Christ, at Citium, in the island of Cyprus. This place having been originally peopled by a colony of Phœnicians, Zeno is sometimes called a Phœnician. His father was by profession a merchant, but discovering in the youth a strong propensity towards learning, he early devoted him to philosophy. In his mercantile capacity he had frequent occasion to visit Athens, where he purchased for his son several of the writings of the most eminent Socratic philosophers. These he read with great avidity; and when he was about thirty years of age, he determined to take a voyage to a city which was so celebrated both as a mart of trade and of science. If it be true, as some writers relate, that he brought with him a valuable cargo of Phœnician purple, which was lost by shipwreck upon the coast of Piræus, this circumstance will account for the facility with which he at first attached himself to a sect whose leading principle was the contempt of riches. Upon his first arrival in Athens, going accidentally into the shop of a bookseller, he took up a volume of the commentaries of Xenophon; and after reading a few passages, was so much delighted with the work, and formed so high an idea of the author, that he asked the bookseller where he might meet with such men. Crates, the Cynic philosopher, happening at that instant to be passing by, the bookseller pointed to him, and said, "Follow that man." Zeno attended upon the instructions of Crates, and was so well pleased with his doctrine that he became one of his disciples. But though he admired the general principles of the Cynic school, he could not easily reconcile himself to their peculiar manners. Besides, his inquisitive turn of mind would not allow him to adopt that indifference to every scientific inquiry which was one of the characteristic distinctions of the sect. He therefore attended upon other masters, who professed to instruct their disciples in the nature and causes of things. When Crates, displeased at his following other philosophers, attempted to drag him by force out of the school of Stilpo, Zeno said to him, "You may seize my body, but Stilpo has laid hold of my mind." After continuing to attend upon the lectures of Stilpo several years, he resorted to other schools, particularly to those of Xenocrates and Diodorus Cronus. By the latter he was instructed in dialectics. He was so much delighted with this branch of study, that he presented to his master a large pecuniary gratuity, in return for his free communication of some of his ingenious subtilties. At last, after attending almost every other master, he offered himself as a disciple of Polemo. This philosopher appears to have been aware that Zeno's intention, in thus removing from one school to another, was to collect materials from various quarters for a new system of his own; for when he came into Polemo's school, he said to him, "I am no stranger, Zeno, to your Phœnician arts; I perceive that your design is to creep slyly into my garden, and steal away my fruit." Polemo was not mistaken in his opinion. Having made himself master of the tenets of others, Zeno determined to become the founder of a new sect. The place which he made choice of for his school was a public portico, adorned with the pictures of Polygnotus, and other eminent painters. It was the most famous portico in Athens, and called, by way of eminence, Στοὰ, "the Porch." It was from this circumstance that the followers of Zeno were called *Stoics*.

In his person Zeno was tall and slender; his aspect was severe, and his brow contracted. His constitution was feeble, but he preserved his health by great abstemiousness. The supplies of his table consisted of figs, bread, and honey; notwithstanding which, he was frequently honoured with the company of great men. In public company, to avoid every appearance of an assuming temper, he commonly took the lowest place. Indeed so great was his modesty, that he seldom chose to mingle with a crowd, or wished for the company of more than two or three friends at once. He paid more attention to neatness and decorum in external appearance than the Cynic philosophers. In his dress indeed he was plain, and in all his expenses frugal; but this is not to be imputed to avarice, but a contempt of external magnificence. Zeno lived to the extreme age of ninety-eight; and at last, in consequence of an accident, voluntarily put an end to his life. As he was walking out of his school he fell down, and in the fall broke one of his fingers; upon which he was so affected with a consciousness of infirmity, that, striking the earth, he said, "Why am I thus importuned? I obey thy summons;" and immediately went home and strangled himself. He died in the first year of the 129th Olympiad. The Athenians, at the request of Antigonus, erected a monument to his memory in the Ceramicum.

ZEPHYRUS, one of the Pagan deities, was represented as the son of Aurora, and the lover of the nymph Chloris according to the Greeks, or of Flora according to the Romans; and as presiding over the growth of fruits and flowers. He is described as giving a refreshing coolness to the air by his soft and agreeable breath, and as moderating the heat of summer by fanning the air with his silken wings. He is depicted under the form of a youth, with a very tender air, with wings resembling those of the butterfly, and with his head crowned with a variety of flowers. As the poets of Greece and Rome lived in a warm climate, they are lavish of their praise of this beneficent deity, and under his name describe the pleasure and advantage which they received from the western breezes.

ZERBST, a city, the capital of a bailiwick of the same name, in the duchy of Anhalt Dessau, in Germany. It stands on the river Ruthe, is surrounded with walls, and is the seat of a superintendent of the superior court of law. It contains two Lutheran, and one reformed church, two hospitals, a gymnasium, 1600 houses, and 8440 inhabitants. It was the residence of the court of the now mediatized prince of Anhalt-Zerbst, and was the birth-place of the empress Catherine II. of Russia. The city has declined since the removal of the court, but has still some manufactures, and four large annual fairs, where the chief commodities are the products of the soil.

ZEST, the woody thick skin quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white wine, as a remedy against the gravel.

ZETLAND, or SHETLAND ISLANDS. The appellation of Zetland, given to this northern cluster of islands, is a corruption of their ancient name. In the oldest northern chronicles, as the Orkneyinga Saga, their denomination is Hialtland, *the Land of the Hilt*, either from some fancied resemblance in the form of the whole group to the hilt of a sword, or from the warlike propensities of the inhabitants. This name was corrupted by Scotish writers of later times into Yetland or Zetland; the letters Z and Y having in the Scotish dialect the same sound, as is well known, in proper names like Menzies, Monzie, Cockenzie, and the like. The Zetland Islands, along with those of Orkney, form one of the counties of Scotland. Exclusively of the small island called Fair Isle, which lies midway between Orkney and Zetland, and is about twenty miles distant from either cluster, they are situated in the North Sea, between the parallels 59° 52′ and 60° 50′ north latitude. The meridian of Greenwich passes through them almost at their extreme east, and they stretch to 2° 11′ west. They are distant from Norway forty-four leagues, from Aberdeenshire forty-seven, and from Leith ninety-six. In number they are more than one hundred, but of these only thirty-four are inhabited. The population of the islands, by the last census (1831), amounted to 29,392. "The climate of the Zetland islands," we quote from the work of Dr Edmonstone, a native of the county, "is very variable and damp, although by no means generally unwholesome to their inhabitants. Spring can scarcely be said to commence until April, and there is but little general warmth before the middle of June. The summer terminates for the most part with August, though sometimes it continues through September. Autumn is a very uncertain period, and winter commences with the middle of October, and occupies the remaining months of the year."

Referring our readers to the article ORKNEY for the general history and present political state of the county, we shall notice what appears most interesting in the principal islands.

The largest island, Mainland, is about sixty miles long, and varies in breadth from twenty-five miles to one hundred yards; the former is the distance from Sandness to the Noup of Nesting, and the latter is the breadth of the isthmus called Mavis-Grind. The bold and precipitous capes called Fitful Head and Sumburgh Head (both celebrated by Sir Walter Scott in his Pirate), the castle of Scalloway, the green vale of Tingwall, the remains of the chapel of the barons of Burgh, Ronas Hill in the parish of Northmavine, and the town of Lerwick with its harbour, fort, and shipping (See LERWICK), are the most remarkable objects on the Mainland. The small islet of Moussa, on the eastern coast of the Mainland, contains the most perfect remaining specimen of those circular towers, with gracefully curved walls, perforated by low galleries, which Scotland can boast. This is undoubtedly Scandinavian, and affords a fair presumption that the similar structures in Glenbeg, Dundornadilla in Sutherland, and other Highland districts, belong to the same people. To the north of the Mainland lies Yell, eight miles in breadth and twenty in length. It is a flat island, with much good sheep-pasture, and some arable land, lying along the shores and coasts of the *voes*, or ocean inlets. In Yell are the remains of no less than twenty chapels or religious houses, small unadorned buildings, in all probability erected long centuries ago, as votive offerings by tempest-tossed mariners, who barely escaped with life.

Still farther north, and somewhat to the east, is Unst, the most northerly of the British islands, ten miles long and four broad. In this island the law-tings or judicial assemblies of Zetland were once held. They were afterwards removed to Tingwall, on the south-west side of the Mainland. In Unst there is much good grazing, and very valuable arable land. At Burness, near Balta Sound, in this island, Biot, and afterwards Captain Kater, in the years 1817 and 1818, instituted a series of experiments in order to determine the variation in the length of the seconds pendulum. Chromate of iron has lately been found, and in considerable quantity, in Unst, and is indeed its chief treasure. South of Unst, and east from Yell, lies the small fertile island of Fetlar. Eight miles south of Fetlar, and distant from the Mainland two or three miles, is Whalsey. The arable land in this island has been cultivated at considerable expense, and admirably improved; and the results shew what care and a judicious expenditure will accomplish, even in this hyperborean region. Whalsey is surrounded by holms or small islands, on one of which, about sixty years ago, a Russian frigate was wrecked, and almost all on board perished. Bressay, five or six miles long by three broad, lies to the east of the Mainland, and the channel between the islands forms Lerwick harbour, or Bressay Sound, one of the safest and most commodious havens in Britain. The principal entrance is a mile wide, and the anchorage is about three miles long. Within the harbour, towards the north, is the sunk rock called the Unicorn, from the vessel of Kirkcaldy of Grange, which was dashed to pieces on it when in pursuit of the infamous Bothwell. To the east of Bressay is the small island of Noss; and on the south-east side of this island lies the holm of Noss, a rock rising almost perpendicularly to the height of 200 feet, and having its summit covered with short rich pasture. The holm is thirty yards distant from the island, and a communication has been effected and is continued in the following way. A daring islander climbed the perpendicular face of the holm, and drove two strong posts into the ground near the edge of the side next to Noss, and a rope having been conveyed from the larger islet, was fastened to these posts, and the chasm was passed. The *craigsman* scorned to take advantage of his success, and attempting to return by the rocks, lost his footing and was dashed to pieces. The rope is annually removed before winter, and the communication is re-opened generally in July. The following is the mode of doing it. A stone is fastened to the *double* or *bight* of a small cord, the ends of which are secured, the stone is flung till the thrower succeeds in getting the attached string beyond the posts on the holm. When this is accomplished, a stronger line is substituted, and a still stronger one, and the process of substitution is repeated, till a rope of the desired strength has been drawn round the posts, and secured to corresponding stakes on Noss. A wooden box called "the cradle of Noss" is then slung upon the rope, and a person getting into this, easily pushes himself backwards and forwards. Dangerous as all this seems, accidents, it is affirmed, seldom happen. Immense numbers of wild fowl frequent the holm, and their eggs, feathers, and young ones, and the pasture afforded to about a dozen sheep, are deemed a recompense sufficient for the trouble and risk encountered in annually erecting this aërial bridge. Almost opposite to Bressay, on the west side of the Mainland, lie the two islands of Burra, separated by a narrow channel, which in one place is so contracted that a wooden bridge is thrown across it to facilitate communication. The soil of these islands is in general of the finest quality, and they produce what in Zetland is regarded as a large quantity of grain. About the middle of the seventeenth century a Dutch squadron was driven by stress of weather on the west side of Burra. Two vessels were lost, but the rest of the fleet succeeded in making a harbour. To the north and west of Burra, and separated from the Mainland by a narrow but troubled strait, lies Papa Stour, an island two miles in length. There are several large caves in this island, open to the sea, which are frequented by numerous seals. One of these caves is lighted from above, by an aperture fifty feet long by twenty broad. Here too may be seen, rising perpendicularly to a great height from its ocean bed, the Stack of Snalaa, a magnificent rock, on the summit of which, from time immemorial, the eagle has had his eyrie. In the bay of St Magnus, tower up the magnificent Drongs, the perforated rocks so finely delineated by Dr Hibbert. Placed far amid the melancholy main is Foula, the most westerly of the Zetland Islands, and with every probability supposed to be the *Thule* of the Romans. At a distance it presents the appearance of five conical hills, the loftiest of which reaches a height of 1300 feet, an immense elevation in appearance, there being no gradual rise, as in inland mountains. "On reaching the highest ridges of the rocks," says Dr Hibbert, "the prospect presented on every side is of the sublimest description. The spectator looks down from a perpendicular height of 1100 or 1200 feet, and sees below the wide Atlantic roll its tide. Dense columns of birds hover through the air, consisting of mews, kittywakes, lyres, sea-parrots or guillemots: the cormorants occupy the lowest portions of the cliffs, the kittywakes whiten the ledges of one distant cliff, gulls are found on another, and lyres on a third. The welkin is darkened with their flight; nor is the sea less covered with them as they search the waters in quest of food. But when the winter appears the colony is fled, and the rude harmony produced by their various screams is succeeded by a desert stillness. From the brink of this awful precipice the adventurous fowler is, by means of a rope tied round his body, let down many fathoms; he then lands on the ledges where the various sea-birds nestle, being still as regardless as his ancestors of the destruction that awaits the falling of some loose stones from a crag, or the untwisting of a cord. It was formerly said of a Foula-man, 'his gutcher (grandfather) gaid before, his father gaid before, and he must expect to go over the sneug too.'" Twenty miles S.S.W. from Sumburgh Head, the southern extremity of the Mainland, lies the Fair Isle, two miles in length, and about three-fourths of a mile in breadth. On this island the duke of Medina Sidonia, the admiral of the armada, was wrecked while attempting to reach home after his disastrous expedition had failed. The crews of his ship reached the shore, but the islanders are said to have murdered them almost to a man, from a conviction that a famine could not otherwise be warded off. The duke was spared, and having wintered in Zetland, he afterwards reached Spain by way of France.

The natural history of Zetland differs little from that of Orkney, to which we refer. The plants in both clusters of islands are, generally speaking, the same; and a similar remark applies to the zoology.

The geology of Zetland has been discussed at great length both by Professor Jameson and Dr Hibbert; and appended to Neill's Tour in these islands is a valuable paper on the subject by Professor Traill. Owing to the variety of the rocks, and the easy access to them which the ocean has thrown open, Zetland presents an interesting field to the mineralogist. Primitive clay-slate, intermixed with a few quartz and hornblende beds, abounds in the southern parts of the Mainland. Ronas Hill, and the greater portion of Northmavine, consist of a hard red granite. In Foula the rocks are all micaceous schistus. Bressay and Ness are composed of sandstone, and much of the shores of Yell and Unst are of serpentine.

It is difficult to give any thing at all approaching to an estimate of the trade of Zetland. Its exports are principally salted fish, oil, tallow, butter, skins, stockings, cattle, sheep, and ponies. The imports are of a very miscellaneous description; and as Zetland produces about one third less grain than its inhabitants require, large quantities of meal and flour are annually introduced.

The fisheries, namely, the whale-fishing at Greenland and Davis Straits, and the herring and haaf or deep-sea fishings at home, employ many hands, and bring much wealth into the country.

Of the state of agriculture in these islands it is impossible to speak in very favourable terms. Shirreff in his Survey says, there is reason to believe that the undivided and consequently uncultivated waste lands amount to more than 400,000 acres. This immense tract is pastured in common by the tenants of the adjoining arable lands, which do not exceed 25,000 acres; and in many places the arable land is *runrig* or interrupted. Little improvement can in such circumstances be expected. Still a few spirited individuals have set an example. The results of their exertions have been most favourable, and are visible; and it is to be hoped that others will be prompted to imitate them. Till the era of the reform bill, Zetland had no representative in parliament, the landholders having no vote for the county-member. This anomaly is now happily removed; and though unwilling to attach undue importance to mere political changes, the writer of these remarks cannot but think, that the alteration produced on the relations of landlord and tenant consequent on the passing of the bill, the inducements now held out to the former to grant leases of some duration, and the more frequent intercourse among themselves and with strangers which an extension (in this case a creation) of the franchise invariably produces; all this will operate favourably both on the commerce and the agriculture of the islands. Owing to their remote situation and their poverty, the lower orders are more dependent on the mere will of those above them than is desirable; but the great change on their political state to which we have already alluded, and other causes now in operation, will, we trust, diminish, if they do not remove, many of the hardships under which they have hitherto laboured. By all who have visited them, the Zetlanders are found to be a warm-hearted, affectionate, honest, and most hospitable people. (D. N.)

ZEUGMA, a figure in *Grammar*, by which an adjective or verb that agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUXIS, a celebrated painter, flourished about 400 years before the Christian era. He was born at Heraclea; but as there have been many cities of that name, it cannot be certainly determined which of them had the honour of his birth. Some learned men however conjecture that it was the Heraclea near Crotona in Italy. He carried painting to a much higher degree of perfection than Apollodorus had left it; discovered the art of properly disposing lights and shades, and particularly excelled in colouring. He amassed immense riches, and then resolved to sell no more of his pictures, but gave them away; saying very frankly, that he could not set a price on them equal to their value. Before this time he made people pay for seeing them; and nobody was admitted to see his Helena without ready money, which occasioned the wags calling his picture *Helen the Courtezan.* It is not known whether this Helen of Zeuxis was the same with that which was at Rome in Pliny's time, or that which he painted for the inhabitants of Crotona, to be hung up in the temple of Juno. This last he painted from five beautiful girls of that city, copying from each her greatest excellencies. Pliny observes, that this admirable painter, disputing for the prize of painting with Parrhasius, painted some grapes so naturally that the birds flew down to peck them. Parrhasius, on the other hand, painted a curtain so very artfully, that Zeuxis, mistaking it for a real one that hid his rival's work, ordered the curtain to be drawn aside, to show what Parrhasius had done; but having found his mistake, he ingenuously confessed himself vanquished, since he had imposed only upon birds, while Parrhasius had deceived even a master of the art. Another time he painted a boy loaded with grapes; when the birds also flew to this picture, at which he was vexed, and confessed that his work was not sufficiently finished, since, had he painted the boy as perfectly as the grapes, the birds would have been afraid of him. Archelaus king of Macedon made use of Zeuxis's pencil for the embellishment of his palace. One of this painter's finest pieces was a Hercules strangling some serpents in his cradle, in the presence of his affrighted mother; but he himself chiefly esteemed his Athleta, or Champion, under which he placed a Greek verse that afterwards became very famous, and in which he says, "that it was easier to criticise than to imitate the picture." He made a present of his Alcmena to the Agrigentines. Zeuxis did not value himself on speedily finishing his pictures; but knowing that Agatharchus gloried in his being able to paint with ease and in a little time, he said, "that for his part he, on the contrary, gloried in his slowness; and if he was long in painting, it was because he painted for eternity." Verrius Flaccus says that Zeuxis having painted an old woman, he laughed so very heartily at the sight of this picture that he died; but as no other of the ancients has mentioned this particular, there is the greatest reason to believe it fabulous. Carlo Dati has composed in Italian the Life of Zeuxis, with those of Parrhasius, Apelles, and Protogenes. This work was printed at Florence in 1667.

ZIEGENHAM, a province of the principality of Hesse-Cassel, in Germany, formerly a sovereign state, which came under the Hessian family in 1540. It is bounded on the north and the north-east by Lower Hesse, on the south-east by Hersfeld, on the south by Great Hesse, on the south-west by Fritzlar, and on the west by Upper Hesse. It extends over 218 square miles, and contains six cities and towns, seventy-three villages, and twenty-two hamlets, with 32,400 inhabitants. The capital is the city of the same name, in a marshy situation. It is surrounded with dilapidated walls, has a castle, in which the archives of the Hessian family are preserved; but only contains 260 houses, with 1280 inhabitants.

ZINC, a metallic substance, formerly considered as one of the brittle metals; or, according to the distinction of the older chemists, a *semi-metal*, or an imperfect metal, because it was found to be destitute of some of the properties of other metals which were considered as perfect. See CHEMISTRY.

ZINZENDORF, NICHOLAS LEWIS, COUNT OF, the noted founder of the German religious sect called *Moravians* or *Herrnhutters*, or, as they pretend, the restorer of that society, was born in the year 1700. From his own narrative it appears, that when he came of age in 1721, his thoughts were wholly bent on gathering together a little society of believers, among whom he might live, and who should entirely employ themselves in exercises of devotion under him. He accordingly purchased an estate at Bertholsdorf in Upper Lusatia, where, being joined by some followers, he gave the cure of the village to a person of his own complexion; and Bertholsdorf soon became conspicuous for a new mode of piety. One Christian David, a carpenter, brought a few proselytes from Moravia: they began a new town about half a league from the village, where Count Zinzendorf fixed his residence among them, and whither great numbers of Moravians flocked and established themselves under his protection; so that in 1732 their number amounted to 600. An adjacent hill, called the *Huthberg*, gave occasion to these colonists to call their new settlement *Huth des Herrn*, and afterwards *Herrnhuth;* which may be interpreted "The guard or protection of the Lord;" and from this the whole sect have taken their name. The count spared neither pains nor money to propagate his opinions: he went himself over all Europe, and at least twice to America; and sent missionaries throughout the world. He died at Herrnhutt on the 9th of May 1760.

ZION, or SION, a very famous mountain, standing on the north side of the city of Jerusalem (Psalm xlviii. 2), containing the upper city, built by King David, where stood the royal palace (Josephus. Psalm xlviii. 2). A part of Zion, situated at its extremity, was called *Millo*, of or in the city of David (2 Chron. xxxii. 5). Modern travellers who have examined the spot say that Zion is the whole of the mountain on which Jerusalem stands at this day, though not to the extent in which it anciently stood on the same mountain, as appears Psal. ix. 12, 15; lxv. 1; lxxxvii. 2, 3; Is. lxii. 1. It is swelled into several eminences or tops, as Moriah, Acra Bezetha, and Zion, a particular eminence or mount, and Zion proper, &c., encompassed on three sides, east, west, and south, with one continued deep and steep valley; by means of which it was impregnable on these three sides, and always attacked and taken, according to Josephus, by the enemy on the north side, where Mount Zion became level, and the vales of Gihon and Jehoshaphat gradually lose themselves. This deep and steep valley incontestably constitutes the compass of the old Jerusalem on those three sides, as plainly appears to any person who has been upon the spot. In opposition to the opinion of former travellers, Dr Clarke thinks that the proper Mount Zion is an eminence entirely without the city, on the south side; and in the valley between this and the city he places the holy sepulchre. That part of the valley which lay to the east was called *Jehoshaphat's*, having Mount Olivet lying beyond it; that to the south *Gehinnon*, and that to the west *Gihon*, from cognominal mountains lying beyond them. At the west end of Gihon, without the city, stood Golgotha or Calvary. The same traveller thinks that very little credit is due to the names given to the different places and objects by the monks. There is another *Zion*, the same with Hermon.

ZISKA, John, a famous general of the forces of the Hussites, was born in Bohemia about the year 1380. His proper name was Trocznow; but he entered very young into the army, and after distinguishing himself on several occasions, lost an eye in a battle, whence he was called *Ziska*, or *One-eyed.* At length the reformation, begun by John Huss, spreading throughout almost all Bohemia, Ziska placed himself at the head of the Hussites, and had soon under his command a body of 40,000 men. With this army he gained several victories over those of the Romish religion, who carried on a kind of crusade against them; and built a town in an advantageous situation, to which he gave the name of *Tabor*, whence the Hussites were afterwards called *Taborites.* Ziska lost his other eye by an arrow at the siege of the city of Rubi; but this did not prevent his continuing the war, his fighting battles, and gaining several great victories, among which was that of Ausig on the Elbe, in which 9000 of the enemy were left dead on the field. The emperor Sigismund, alarmed at his progress, caused very advantageous proposals to be made to him, which he readily accepted, and set out to meet Sigismund, but died on the road, on the 11th of October 1424. He ordered that his body should be left a prey to the birds and wild beasts, and that a drum should be made of his skin, being persuaded that the enemy would fly as soon as they heard the sound. It is added that the Hussites executed his will; and that the news of this order made such an impression on the disturbed imaginations of the German papists, that in many battles they actually fled at the beat of the drum with the utmost precipitation, leaving their baggage and artillery behind them.

ZITTAU, a city of the kingdom of Saxony, in the province of Lausitz. It stands on the river Mandau, near to where that stream falls into the Neisse. It is on an elevated spot, 763 feet above the level of the sea, is surrounded with double walls, contains eight churches, a hospital, an orphan-house, 1140 houses, and in 1834 had 8508 inhabitants. The town is well built, has several institutions for education, and some extensive manufactures of linen and cotton, large breweries, and several paper-mills.

ZLOCZOW, a circle of the Austrian kingdom of Gallicia, bounded on the north and north-east by Russia, on the south-east by Tarnapol, on the south by Brezazari, and on the west by Lemberg. It extends over 2024 square miles, comprehends six cities, nineteen market-towns, and 339 villages, with 208,950 inhabitants. It is a level and moderately fertile district, watered by the river Bug and its numerous tributary streams. The capital, likewise called Zloczow, is situated between woods and marshes. It contains a Catholic and two Greek churches, an ancient castle, 1107 houses, and 6440 inhabitants. Long. 24. 47. 40. E. Lat. 49. 49. 45. N.

ZNAYM, a circle of the Austrian province of Moravia, extending over 1320 square miles, comprehending eight cities, thirty-six market-towns, and 369 villages, with 137,980 inhabitants. The capital is the city of the same name, on the river Taya. It is surrounded with walls, has an ancient fortress, and contains 512 houses, with 5430 inhabitants, who make considerable quantities of woollen cloths. Long. 15. 57. 46. E. Lat. 48. 51. 15. N.

ZODIAC, a broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto, at such a distance from it as to bound or comprehend the excursions of the sun and planets. See Astronomy. It is a curious enough fact, that the solar division of the Indian zodiac is the same in substance with that of the Greeks, and yet that it has not been borrowed either from the Greeks or the Arabians. The identity, or at least striking similarity, of the division, is universally known; and Montucla has endeavoured to prove that the Brahmins received it from the Arabs. His opinion, we believe, was very generally admitted; but Sir William Jones has adduced a variety of arguments which seem to prove that neither of those nations borrowed that division from the other; that it has been known among the Hindus from time immemorial; and that it was probably invented by the first progenitors of that race, whom he considers, before their dispersion, as the most ancient of mankind. See Asiatic Researches, vol. ii.

ZOMBAR, or Sombor, a city of the Austrian kingdom of Hungary, the capital of a circle of the same name, in the province of Lower Danube. It stands on the navigable canal Francis, and contains a Catholic, a Greek, and a Lutheran church, with a free school of some celebrity. It numbers 2961 houses, with 15,106 inhabitants, chiefly of German origin, who carry on extensive trade in corn and cattle. Long. 21. 9. 48. E. Lat. 48. 8. 32. N.

ZONARAS, Joannes, a miscellaneous Greek writer of considerable note, flourished at Constantinople about the beginning of the twelfth century. Under the emperor Alexius Comnenus, who died in 1118, he rose to the distinction of being nominated great *drungarius*,[1] and chief secretary; but after the death of his wife, he retired to a monastery, and there closed his earthly career. His principal work is his Χρονικὸν, or Annals, deduced from the creation of the world to the death of his imperial patron. The earlier portion of it we cannot easily suppose to be very important; but that which relates to the history of the Greek empire is not without a considerable share of historical value. The *editio princeps* was published by Wolfius, Basil. 1557, 3 tom. fol. This was succeeded by the valuable edition of Du Cange, Paris. 1686, 2 tom. fol.; which was reprinted in the Venice edition of the Byzantine historians. Zonaras is well known to canonists by his work, "In Canones S. S. Apostolorum et sacrorum Conciliorum Commentarii." Lut. Paris. 1618, fol. These commentaries are inserted in Bishop Beveridge's Pandectæ. Some of his works, one in verse, may be found in other collections. See particularly Cotelerii "Ecclesiæ Græcæ Monumenta," tom. ii. p. 483, tom. iii. p. 465. A publication more interesting to philologers remains to be specified: "Jo. Zonaræ et Photii Lexica, ex codicibus manuscriptis nunc primum edita, observationibus illustrata, et indicibus instructa." Lipsiæ, 1808, 3 tom. 4to. The first two volumes contain the lexicon of Zonaras edited by Tittmann; the third volume contains that of Photius edited by Hermann. In the article Photius, this and another important publication have both been overlooked. "Φωτίου τοῦ Πατριάρχου Λέξεων Συναγωγή. E codice Galeano descripsit Ricardus Porsonus." Lond. 1822, 2 part. 8vo.

ZONE, a division of the terraqueous globe with respect to the different degrees of heat found in its different parts. The zones are denominated torrid, frigid, and temperate. The torrid zone is a band surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is 46° 58′. The equator, running through the middle of it, divides it into two equal parts, each containing 23° 29′. The ancients imagined the torrid zone uninhabitable. The temperate zones are contained between the tropics and the polar circles. The breadth of each is 43° 2′. The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46° 58′.

ZOOLOGY is that part of natural history which relates to animals. See Animal Kingdom.

---

ZOOPHYTES.

When the word *Zoophyte* began to be used by naturalists, it designated a miscellaneous class of beings, which were believed to occupy the space between the animal and vegetable kingdoms, and in which the characteristics of the subjects of each met and were intermingled. They were of a "middle nature," not because of their outward resemblance to plants, but because they were deficient in the more obvious qualities of animals, and were apparently more influenced by exterior forces than by any volitions springing up within. Almost insensible and immotive, their weak and obscure life was merely regarded as one of vegetation, engendered in them by putrefaction or fermentation, and unsusceptible of the volitions and passions which move and agitate higher entities. Thus the term indicated a mingled life or constitution, and had no reference to figure; but some time after it had been allowed on all hands that the productions in question were "better than mere vegetives," another class of objects, hitherto supposed to be altogether vegetable, was ascertained to be of animal origin; and as their similitude to mosses and lichens, to sea-weeds and mushrooms, was undeniable, and indeed so remarkable as to have long veiled their nature from us, so the term Zoephyte was transferred to this newly-discovered order, and has since been applied by the majority of English authors to it alone. With continental naturalists, however, the word has still its widest application, embracing, in their nomenclature, not merely those polypiferous beings which cover the bottom of the ocean with a singularly exact mimickry of vegetation, but also the star-fishes and sea-urchins, the sea-figs and sea-nettles or jelly-fish, and even the intestinal worms. It is in this wide acceptation that the word is employed by Cuvier and Blainville; and we use it here with the same latitude, agreeably to the plan indicated in our article Animal Kingdom.

The Zoophytes, then, as defined by Cuvier, form a sub-kingdom co-equal with the two divisions in the animal kingdom named *Radiata* and *Acrita* by Macleay. The classes included in it have less of a common resemblance than the classes of any other sub-kingdom, so that in the great variety of structures which they present to our study, we seek in vain for any one character that shall connect them together. The most general character is that which has conferred upon them the synonyme of "Radiated Animals," given because the organs of locomotion, and even the internal viscera, are arranged very often in a circular disposition round a centre, so as to give a sort of radiant appearance to the whole body, or to some part of it. The nervous system is at the best only rudimentary, and is demonstrable only in a few genera of three of the classes. Thus its existence has been shewn in several species of intestinal worms, where it consists of one or two ganglions placed near the mouth, and from which diverge a few filaments, and one or two longer chords that follow down the length of the body. In the more normal Zoophytes, the nervous system forms a circle round the oral aperture, whence slender filaments radiate towards the circumference, rarely dividing into a few branchlets, and losing themselves in the parenchyma long before they reach the periphery. But in the larger number of this sub-kingdom no trace of such a system is discoverable, unless, with Macleay, we find it in the "minute granulations" which bespeck their homogeneous, mobile, and irritable pulp, and "which may be considered as the nervous molecules dispersed over, or, as it were, confounded with, the substance of these animals, so as to impregnate the whole with sensibility." This property of animal life they accordingly enjoy in a high degree of development, while their instincts are reduced almost to a nullity; and in regard to the external senses, it may with truth be said of most of them, that they are "sans teeth, sans eyes, sans taste, sans every thing."[1] They are almost, without exception, indolent and slow of movement, some advancing by the writhings and contractions of a soft body; some by the play of invisible cilia, which garnish, in set rows, their appendages; and others by the aid of hollow extensible tentacular suckers; while many among them are rooted, and as fixed as the plants whose graceful forms they seem to envy, and strive to emulate.

There is, according to Cuvier, no true system of a circulation in any Zoophyte; but Nordmann has delineated a very beautiful system of vessels, apparently sanguiferous, in some intestinal worms; and a similar one has been shewn to exist in the Planariæ, and in some external parasites, as in the genus Phylline. Among the more regular Zoophytes, we find very generally a system of aqueducts, which permeate and ramify through the body, but which are distinguished from any circulatory vessels by having a direct communication with the water in which the animal floats. This system is mainly subservient to locomotion; but to a certain extent it must supply the purposes of a circulation in higher organisms, for the fresh currents of water which it leads within the body will oxygenate, and render fit for assimilation the nutritive materials that come within their reach and influence. The Holothuriæ afford a good illustration of this double function, for they have two aquiferous systems; one connected with the intestines, and in correspondency with the organs of respiration; the other subservient only to the turgescency and relaxation of the organs that perform the offices of feet. This latter system only, it is said, can be discovered in the star-fishes and sea-urchins; while the vascular canals that ramify like veins through the clear gelatinous bodies of the sea-jellies, originating in the alimentary cavities, and running in divergent lines to the circumference, seem to constitute a system accessory principally to respiration and nutrition. In many fixed polypiferous Zoophytes, there are also found ducts for introducing water within the body; and in others, where these aquiferous ducts have no existence, the surface or appendages of the little creature are clothed with minute vibratile cilia, that constitute a real breathing apparatus.

Some families, such as the holothuriæ, the sea-urchins, and several intestinal worms, as well as some polypiferous Zoophytes, have a mouth, an alimentary canal, and an excrementitious or anal orifice; others have a kind of stomach with only one orifice, which is by turns a mouth and a vent; in a great number there is merely a digestive cavity, excavated in the substance of the body, for the reception of the food, which enters sometimes by one and sometimes by several orifices; and in other Zoophytes of abnormal character there is no mouth, and we suppose that these must imbibe their nutritive matter by pores on the general surface.

The individuals of some species of intestinal worms are male and female, but in general the Zoophytes are hermaphroditical and oviparous. Some are propagated by a sort of gemmation, or by self-division. Many of them are compound animals; a kind of monster, in which often hundreds of individuals consociate, and are organically connected together, so as to make one living mass or commonwealth, that possesses all things in common, and usually shoots up in an arborescent form.

Intestinal Worms.

Having premised these few remarks, we proceed to treat of this sub-kingdom under the following divisions or classes:—I. The Intestinal Worms; II. The Echinodermata or Sea-stars; III. The Acalephæ or Sea-jellies; IV. The Polypes or Zoophytes properly so called; V. The Sponges; and VI. The Lithophytes.

I.—INTESTINAL WORMS.[1]

It affords a striking illustration of the wide diffusion of animal life to have ascertained the fact, that almost every species of the vertebrated orders, and very many of the inferior classes, afford, either within or on the surface of the body, a place of nativity and domicile to one or more living creatures, framed with especial adaptation to the circumstances of their destined abodes. They do not however infest every animal indiscriminately; for, on the contrary, the parasites of almost every species are peculiar to itself, or they are confined to a few of analogous habits and structure. There are some partial exceptions. Thus, the fluke (*Distoma hepaticum*), so common in the liver and gall-ducts of sheep and other domestic cattle, is found occasionally in the liver of man, but comparatively so small as to have been sometimes looked upon as a distinct species. The *Ascaris lumbricoides* of man is identical with that found in the horse, the ox, and the sow; his *Trichocephalus* occurs in the ape; the *Cysticercus* of the cellular tissue is common to him and the ape and pig; and the *Strongylus giganteus* has a wide range, not fearing man, and rioting in the kidney of many of the inferior animals. Frœlich took from a tropical parrot an *Ascaris*, which was apparently identical with a worm that Rudolphi found in our domestic pigeon; and similar examples, more especially from among the parasites of fishes, might be instanced.[2] But there is no example of a worm being common to a warm and a cold-blooded animal; nor does the same worm ever occur in the mammalia and in birds, nor in amphibia and in fishes; nor, indeed, in the species of any two well-distinguished classes; and so also it is ascertained that the parasites of the carnivorous animals (with the sole exception of the renal parasites) are in every instance different in kind from those of the vegetable feeders. It must not however be concluded, that of the animals liable to the attacks of intestinal worms, every individual is vermigerous. On the contrary, the Entozoa in general are comparatively of rare occurrence, and many are so rare that few helminthologists, of however wide research, have ever met with them. Mr Lawrence has seen a female, who from time to time has voided many hundreds of small worms (*Spiroptera hominis*) from the urinary bladder;[3] but, so far as is known, no other human being was ever so afflicted. Goeze found in the boar a *Trichocephalus*, which Rudolphi has sought for in vain both in wild and domestic swine; and he tells us he had dissected innumerable mice in a fruitless search after their *Trichocephalus*, described also by the first-named naturalist.[4] These are undoubtedly extreme cases, but they place in a strong light the partial and accidental diffusion of these creatures. What circumstances determine them to select one individual in preference to another, are unknown, though reasons enough have been stated, of all which it may be safely said that the facts adverse to their admission are almost as many as those in their favour. There is no denying that worms in general often infest the delicate and sickly; that youth is favourable to the evolution of some, and maturity to that of others; and females may be more verminous than males; but the contraries are numerous, and the lovers of statistics have not yet balanced the proportions. A crude farinaceous diet has been much blamed, and we should suppose justly; yet the poor of Scotland, who subsist much on such a diet, are not more wormy than the better fed poor of England. Rich moist pastures are said to be favourable to the generation of the fluke in our sheep and cattle; but this is only the case with some pastures, which, in every district, have acquired this bad pre-eminence, and on which certainly our herds cannot be fed many days without the certainty of being tainted. Salt pastures are, on the contrary, unfavourable or destructive to the fluke and worms in general; nor in man does any cause apparently more certainly predispose the body to their visitation than an unsalted innutritive diet. “Salt,” says Dr Paris, “when taken in moderate quantities, promotes, while in excessive ones it prevents, digestion: it is therefore tonic and anthelmintic, correcting that disordered state of the bowels which favours the propagation of worms.” And as an instance of the results of its want, Lord Somerville adduces a punishment which formerly existed in Holland. “The ancient laws of that country ordained men to be kept on bread alone, *unmixed with salt*, as the severest punishment that could be inflicted upon them in their moist climate; the effect was horrible: these wretched criminals are said to have been *devoured by worms*, engendered in their own stomachs.”[5]

The extrinsic causes which give a predisposition to worms are as little known as those which act immediately on the body. Very few avertebrated animals are vermiparous, while there is probably no species of vertebrate that is exempted from parasites. Of the latter class, such species as have been reduced to domesticity, or are retained captive, are more subject to worms than the wild and untamed; and fishes appear to be pre-eminently infested with them. It is not yet determined that the same parasites infest the same animals in different and remote countries, although this is probably the case; but a few facts, relating principally to the human species, seem to prove that climate has a certain influence over their generation. The *Filaria medinensis*, or Guinea-worm, is only found under the torrid zone, in Asia and Africa; and the *Furia infernalis* is peculiar to Lapland.[6] *Ascarides* prevail to such an extent in Abyssinia, as to regulate in some degree the movements of the inhabitants; and in the West India islands, intestinal worms in general are much more common than they are in Europe. We know, on the evidence of Vallisnerius, that *Ascarides* are very frequent in the calves of Italy; while those born from the cows of Germany, says Rudolphi, are rarely infested with them. Hasselquist tells us that when in Cairo he was told that three fourths of the inhabitants were diseased with *Tænia solium;* and “I have been informed by my friend Dr Knox,” says Dr Hodgkin, “that our troops which were stationed in and near the Cape were generally infested by these animals.”[7] Egypt and Africa may then perhaps be considered as the lands of choice of this Tænia, which however has spread, though in smaller numbers, over Germany, Holland, England, and France. In the latter country, it occurs, but not simultaneously in the same individual, with the *Tænia lata*, Linn.—a species of extreme rarity in the English, Dutch, and Germans, but very common in the natives of Switzerland and

Intestinal Worms.

Russia.[1] If any evidence can be drawn from the silence of Otho Fabricius, it would seem that the Greenlanders are not subjected to the tape-worm, but they breed the Ascarides abundantly.

Intestinal worms, as their name implies, are found principally in the alimentary canal, and the viscera subservient to its functions. There are species, however, which have their appropriated seats in the cellular and adipose and serous tissues, and in the parenchyma of the most secret organs. One species peoples in myriads the voluntary muscles, and more than one has penetrated the heart; several develope themselves in the lungs and air-passages, in the liver, the kidneys, and the brain; one or more have entered the blood-vessels or aneurismal tumours connected with them;[2] some float in the humours of the eye; and more than one loathly worm bathes unharmed in the acrid excretion of the urinary organs. If indeed we except the bones, the cartilages, and ligaments, no organ seems exempted from the occasional attacks of worms, unless it be the spleen, in which, according to Rudolphi, no worm has yet been discovered ever to take up its abode. These parasites may in one sense be considered as accidental, since they are found in certain individuals only of the species they infest; and there can be no doubt, although their evil deeds have been frequently much exaggerated, that they become not seldom the cause of serious or fatal disease. And here we may cursorily notice an opinion which has found its advocates in every period of the history of medicine, that most contagious diseases, fevers, and plagues originate from animalcules introduced into the body, and are propagated by their communication to other bodies through the medium of the atmosphere. Linnæus was a believer in this hypothesis, which has recently been supported, with much ingenuity, by Dr Holland, who however properly remarks, that "though the course of discovery has recently been approaching, in some points, nearer to the hypothesis in question, it still furnishes nothing beyond stronger presumptions and more numerous analogies" in its favour.

If animalcules can be so pernicious, and we admit that no more probable cause of many pestilences, and especially of cholera, has been assigned, their influence is, according to physiologists, more than counterpoised by the share which another class of them has in the continuance and propagation of the species. This class is by naturalists named the *Spermatozoa*, of constant and invariable presence in the seminal fluid of every animal capable of propagating its kind; but they are absent in that of the mule, and of other animals which may be sterile from age or the season of the year. Like the accidental Entozoa, the Spermatozoa of every animal has its peculiar characteristics, but the differences between them are comparatively slight. "They all agree in having slightly oblong and flattened heads, with lengthened tails, tapering so as to become nearly or quite invisible with the best glasses; they possess active powers of motion, and are evidently endowed with sensation. No trace of organization has yet been discovered in them, probably on account of their extreme minuteness. Whether essential to generation or not, they may be regarded as the parasites of the tubuli semeniferi."[3]

The origin of the Entozoa within animal bodies, and their viscera, has for long been the subject of much debate and curious speculation. It was a hasty disposal of the question to say that they were no other than the worms of stagnant waters, of marshes, and of vegetable roots, introduced within the body, either in their perfect or egg state, but altered in their appearance and character by the genial heat and other novel circumstances by which they were now surrounded. Though this explanation had the support of Linnæus, and has lately found a strenuous advocate in one of the most learned men that ever graced the medical profession, it has been long known to be quite untenable; for no fact is better ascertained than that intestinal worms are found solely in animal bodies, where only they can live and propagate. The instances to the contrary which have been alleged, of tape-worms and flukes living in marshes, and of earth-worms in our bowels, are known to rest on fiction or incorrect observation; so that, in the discussion of the question, it must be assumed as a fact, that the worms are born in, and peculiar to, the places where we find them. This assumption presented no difficulty to the earlier naturalists, who were unanimous in the belief that all worms were the results of a putrefactive process;

> putrefaction into life ferments,
> And breathes destructive myriads;

or of spontaneous generation; the spawn of a superabundant phlegm, vivified by the heat and fermentation of the belly. But to this ancient doctrine the experiments of Redi on the generation of insects gave the death-blow.[4]

Intestinal Worms.

To explain the beginning of these worms within the body on the common doctrine that all created beings proceed from their likes, or a primordial egg, is indeed so difficult, that the moderns have been driven to speculate, as our fathers did, on their spontaneous birth; but they have revived the hypothesis with some modification. Thus it is not from putrefaction or fermentation that the Entozoa are born, for both of these processes are rather fatal to their existence, but from the aggregation and fit apposition of matter which is already organized, or has been thrown from organized surfaces. Thus Buffon applied his doctrine concerning organic molecules to account for their genesis. Milk, he tells us, "consists entirely of organic and prolific matter, which, when not properly digested by the stomach, and applied to the nourishment and growth of the body, assumes, by its natural activity, other forms, and produces animated beings, or worms:" hence their commonness in the bowels of children; and their origin in the most hidden organs has the same source, for the "living organic particles" may, from various causes, be forced too abundantly to any part of the frame, and living creatures in that part are the result of their union. Rudolphi has adopted an opinion very similar to that of Buffon; for it appears to him that the objections which their history furnishes to a belief in their sexual propagation are insurmountable, and that we must of necessity believe in their spontaneous appearance, or rather in their production from the fit apposition of organic particles that have not been assimilated with the parent body, or from the separation from it of organized particles, which, retaining their proper life, become the germs of an entozoan in situations and under circumstances favourable for their development and metamorphosis. Their origin in this manner is not more wonderful, or more inexplicable, than that of many of the inferior animals from sections of themselves. The Nais, the Planaria, and the Hydra, furnish examples of animals of as perfect organization as worms being thus propagated; for if a small portion is cut away from any species of these genera, and placed in a suitable position, it will continue to live and grow, and develope new organs, until it has acquired in every respect the form and structure and habits of the animal from whence it was separated. Now particles of matter fitted by digestion, and their transmission through a living body, for immediate assimilation with it, or flakes of lymph detached from surfaces already organized, seem neither to exceed nor fall below that simplicity of structure which favours this wonderful development; and the supposition that like the morsels of a Planaria, they may also, when retained in contact with living parts, and in other favourable circumstances, continue to live and be gradually changed into creatures of analogous conformation, is surely not so absurd as to be brought into comparison with the metamorphoses of Ovid.[1] It is a speculation fairly open to inquiry; and indeed one main argument in favour of the spontaneous generation of Entozoa, is the admitted inadequacy of all other hypotheses to explain the facts. Is it possible to believe of a worm which has been found, during the nineteen centuries of the world's age, in one or a few individuals only, that its eggs can have been transmitted from generation to generation, and be thus so very rare in its perfect state? But we have one proof at least that a change of condition in an animal is capable of generating a worm, for a good authority assures us that a parasite found in the flesh of the domestic swine is not to be found in the wild race;[2] and Dr Jenner ascertained that he could produce hydatids and fluke-worms at will in rabbits by feeding them *solely* on green succulent food.[3] How but from innate workings are we to explain the first origin of worms that have neither sexual organs nor ova, but like the hydatid, increase from buds that pullulate from the inner surface of the vesicle that contains them? And Rudolphi has even seen what he believed to be young nascent Tæniæ germinating from the villous surface of the bowels. We think the hypothesis is supported also in some degree by the fact, that the origin of Entozoa in general is favoured by all causes which tend to disturb the equality between the secerning and absorbent systems. Thus there is great reason to believe that some inflammatory action of the liver, of the eye, and of other wormed viscus, precedes the evolution of parasites in them; and it is well known that a morbid state of the alimentary canal, especially an abundant secretion of unhealthy mucus, is connected with the production and increase of all intestinal worms, so much so that Broussais believes an inflammatory state of the mucus membrane to be even an essential condition to their existence. It is obviously necessary to suppose that there are unknown conditions or laws regulating this, the spontaneous growth of worms within us, so that a certain uniformity in the products is the result; but it seems not more difficult to admit the existence of such laws, overruling the destiny of unappropriated organic matter, than their existence and rule over the shred of a Planaria severed from another's body. That there are such laws of regulation, we infer from the fact that the detached portions of a Planaria, a Hydra, or a Nais, invariably evolve into their respective species; and from the analogous fact that the worms of the different cavities and textures are usually dissimilar, as might have been expected from the dissimilarity in the structures from which their unformed and unseminated embryos are separated.[4]

[2] "On Animals in the Blood," see the *Lancet* for August 1840, p. 778.

[3] Hodgkin's *Lectures* vol. i. p. 213. On these animated bodies, the reader will find ample information in Blainville's *Manuel d'Actinologie*, 573, &c.

[4] Of various hypotheses of the earlier writers, Le Clerc has given an excellent account in his chapter xiv., "on the origin of Worms in animal bodies." *History of Worms*, trans. p. 329, &c.

The variety in the exterior forms of intestinal worms is sufficiently great to form the basis of their classification into subordinate divisions. Thus we have the round or cylindrical worms (*Nematoidea*); the sacciform with prickly proboscides (*Acanthocephala*); the flat or fluke worms (*Trematoda*); the tape-worms (*Cestoidea*); and the cystic or hydatids (*Cystica*). In very few of them are there any external appendages, either to diffuse or heighten their sensibilities and perceptions, or to assist in locomotion;[5] but we can distinguish in all of them a head, a body, and an anal extremity; in some there is a neck; in the Trematodes, one or two ventral suckers; and in some the organs of generation are protruded. The skin is commonly white, smooth, thin, and moist, but coriaceous in many of the Acanthocephala, and sometimes roughened with reverted prickles. Minute black points, suspected to be visual organs, bespeckle the anterior extremity of some non-parasitical genera (*Planariæ*) often classified with the flukes; and similar specks have been discovered on a few true Entozoa at certain stages of their development. Thus they are of a brilliant lustre in the *Phanoglene* and *Enchelidium*; and traces of them are visible in the *Gyrodactylus auriculatus*, in several *Cercariæ*, in the *Polystoma integerrimum*, in the young of many *Distomæ*, *Monostomæ*, and *Amphistomæ*, and in the *Scolex polymorphus*.[6]

The internal structure of the Entozoa is as various as their outward form, and in some degree of harmony with it, as will be proved when we come to explain the characters of their classification. It ranges from a homogeneous structureless tissue, such as composes the whole of a zoosperm, to that of an animal with organs of defined limits and function, such as we find them in a nematoid worm, where there are distinct muscles, a perfected apparatus of digestion, and a system of generation on male and female individuals. In a very few intestinal worms, anatomists have recently demonstrated the existence of a slightly developed nervous system. In others, there exists a system of vessels, in which an obscure circulation of a colourless fluid has been seen; but in none of the class is there any trace of a distinct respiratory organ,[7] the functions of which are performed by the skin or surface. The genera whose habitat is the alimentary canal, may have a slightly oxygenated atmosphere to breathe;[8] but such as live in the muscles, in the humours of the eye, or in the brain, no uncombined air can reach; and we are forced to conclude that all the oxygen they require for existence is communicated to them through the fluids they feed on, or from the blood as it circulates over the surfaces with which they are contiguous, or from the medium in which they float. They doubtless require but a small supply, for the heat that is evolved by respiration in other animals is here furnished by the warm abodes they live in; and their food, consisting of chyle, lymph, and excretions in a recent state, is already half prepared for assimilation. We know that their food must be of this soft and liquid nature; for many worms, having no oral aperture, seem to imbibe all their nutriment through minute pores in the skin, or by the process of endosmose; and the whole of what they imbibe is probably assimilated. Even in such worms as have a mouth, this is never armed with cutting or triturating instruments, but constitutes a simple pore for the entrance of a soft material upon which suction can operate. As in the nematoid worms there is both a mouth and an anus, we may conclude, that of their food some part is feculent and excrementitious; and the same inference may be made from every species of similar structure. The Trematoda or flukes have no anus, and their mouth is certainly ill defined, but they have an alimentary canal, ramified in a dendritic fashion; and Rudolphi believes it to be proved, by the colour of the matter in these vessels, that their food is also partly excrementitial, for the worm, naturally colourless, is often dusky, or variously tinctured by the nature of its food.[1] It is singular that this order appears to receive no part of its nourishment from cutaneous absorption, a mode of supply very general in the class, and especially remarkable in the order Acanthocephala. When a specimen of an Echinorhynchus is taken fresh from the bowels, it is small, flattish, and flaccid; but shortly after being immersed in a glass of water, it has become larger, swollen, and distended like a sac; and the most conclusive experiments have proved that the water of distention could only have passed inwards through the skin, the structure of which is peculiarly adapted to the office. If any part of the skin of the *Echinorhynchus Gigas* is held up opposite to the light, and examined from the internal side with a common lens, we perceive a remarkably elegant net-work of vessels, sprinkled over with minute pearl-like vesicles, which are, as it were, the centres of the anastomosing branchlets, or perhaps merely dilatations of the vessels at their points of coalescence and union.[2]

---

[1] See an Essay "on the Equivocal Generation of Entozoa," by Dr Drummond, in the *Annals and Magazine of Natural History*, vol. i. p. 101-108; and Dr Good's *Study of Medicine*, vol. i. p. 292, &c. The argument, as handled by Dr Drummond, does not satisfy us; and the analogies adduced to invalidate the doctrine of equivocal generation by Dr Good seem far fetched, and some of his alleged facts are not true. The remarks of Andral in favour of their spontaneous origin are strongly stated. See the article "Hydatids" in *Cyclop. Pract. Medicine* vol. ii. p. 440.

[2] *Cysticercus cellulosæ*: "The fact of its being found in the swine which man has domesticated, and not in the wild race, appears to furnish an instance of organized bodies which have been formed long after the general creation." Blumenbach's *Elem. of Nat. History*, trans. p. 243. The fact has been contradicted; but the history of insects and infusory animalcules furnishes us with many similar, so that the argument is not invalidated.

[3] *Cyclop. of Pract. Medicine*, vol. ii. p. 438.

[4] The reader will find the subject discussed at great length by Rudolphi in cap. xviii. of his *Historia Nat. Entozoorum*, vol. i. p. 370–416.

[5] The *Phanoglene*, which lives in the larvæ of some neuropterous insects, has some prolongations like antennæ; and Diesing has described some genera (*Ancyracanthus*, *Heterochoilus*) with heads furnished with filaments of various forms.

[6] Lamarck's *Anim. sans Vert.* iii. p. 546, note 1, 2d edit.

[7] Respiratory tracheæ, similar to those of insects, have been ascribed to some of the nematoid worms, but erroneously. See Rudolphi *Entoz. Synopsis*, p. 579, &c.

[8] M. Chevreul, however, found no oxygen in the gas of either the small or great intestines of three different subjects. See Bostock's *Physiology*, vol. ii. p. 490.

The nematoid and acanthocephalous worms have distinct sexes; but the Trematoda and many Cestoidea are androgynous, that is, each individual of the species possesses the organs peculiar to both sexes, and may of itself fecundate its ova, although, with regard to some of them, it has been supposed that the union of two individuals is necessary, as is the case with the slug and snail. In other worms, the female or reproductive organs exist alone; and in the cystic Entozoa no generative apparatus has been provided. "They would seem to be gemmiparous, and to have the reproductive power diffused over the whole cyst, at least in the Acephalocysts, in which the young are not developed from any special organ, or limited to any particular part of the cyst."

The great majority of the higher Entozoa are oviparous; but we have several exceptions among the Nematoids, and one at least among the fluke-worms, which are viviparous. The distinction is however immaterial, for in both kinds the ovaries possess a similar structure, and the eggs accumulate in them in the same fashion. In the oviducts of the viviparous Cucullani, as of the oviparous Echinorhynchi, there are found the same bodies which Rudolphi conjectures to be cotyledons, or little placentæ, into which the ovules are fixed, so that even in this respect no difference exists. The ovules of the oviparous species are of two kinds, containing either an unformed and inconspicuous embryo, or one that is fully formed, but motionless. The ovules of the viviparous species, on the other hand, contain a moveable embryo.

The number of ova produced by a single worm is sometimes prodigious, and almost incredible. *Ascaris lumbricoides* contains, when pregnant, many thousands; *Ascaris nigrovenosa*, according to Goeze, may have 700 living young at a birth; and the *Cucullanus* as many. But what are these to the calculations of Dujardin,[3] who supposes that one *Tænia serrata*, with its 200 articulations, may contain in the united chain not less than twenty-five millions of ova? And it is in fact not uncommon to find eight or ten of these productive monsters in one poor dog. From this fertility we might conclude the numbers within the body of those animals which they infested would be fearfully great; but this is seldom the case, and least of all with those very species that we have instanced as so marvellous in their productive powers. The Tænia or tape-worm is often solitary, and rarely numerous in any individual. It is not difficult to reconcile this apparent contradiction of means and end, when we call to recollection the numerous accidents to which both worms and eggs are exposed, from the nature of their sites; how many undeveloped ova, how many young, how many adults, must daily pass away.

We have already slightly indicated the diseases that may arise from their presence and multiplicity, an injury that some physico-theologists would fain persuade us is countervailed by a series of benefits that animals derive from their parasites. One gravely tells us, that by their motions they cause a gentle irritation, in aid of the intestinal functions, which, moreover, may stimulate the other viscera to the discharge of their duties, and prevent their falling into a state of inaction favourable to the commencement and increase of organic diseases. Another insists that the Entozoa drink up the superabundant chyme, chyle, or mucus, in the bowels. Another believes that they were created as a wholesome check on the pride and vanity of man, as trials of his patience and other virtues, and "finally to secure to him an entrance into an immutable and eternal state of felicity when that of probation is at an end, so that the gates of death may be to him the gates of peace and rest!"[4] Now it may be commendable to look for good in every thing; but this, we think, is looking rather too far, looking also into a sort of kaleidoscope, in which we see all beautiful though unstable pictures patterned out of worthless things.

The relationship of the Entozoa with other animals is involved in much obscurity, but we cannot therefore concur with Bäer in his proposal to exclude them from a natural classification of the animal kingdom; nor do we exactly understand Rudolphi's notion when he says they constitute a peculiar fauna, rather than any order or class parallel with the ordinary divisions of systematists. If the zoosperms are to be reckoned distinct beings, they must probably go to throng the chaos of infusory animalcules; and Dujardin has discovered in the earth-worm and in the slugs a parasite (*Albertia*) that combines with the structure and habits of an entozoon many of the peculiarities of the rotatory animalcules. The hydatids may represent the hydraform polypes; the tape-worm the *cestum Veneris* of the gelatinous medusæ; the Acanthocephala have some ex-eric resemblance to the sipunculidous genera of the radiated animals; the Nematoids a nearer one to the Annelides; and the Trematoda have, with a very general yet erroneous assent, been made members of a family that embraces the Planariæ—leech-like natives of fresh and salt waters—which Mr Swainson errs no less in arranging with the mollusca. Their affinities being thus so remote and uncertain, we are not surprised to find the classification of the intestina unsettled; but from among the many that have been proposed, we only select two for exposition here; that, namely, of Rudolphi, which has been most generally approved; and that of Cuvier, for this, from its wider scope, will afford us an opportunity of noticing some tribes, remotely perhaps allied to the true worms, but which only now come within the plan originally laid down for our guidance.

---

[1] Dr Drummond doubts whether the colour is dependent on the contents of the intestine. "It is certain that in a mass of individuals (of Echinorhynchus acus) found in the same portion of intestine, considerable diversity of colour prevails; and where there has been only a transparent mucus present, I have found specimens of a pure white, and others of a bright orange." *Mag. of Nat. Hist.* n. s. ii. p. 519.

[2] Rudolphi *Entoz. Synop.* p. 582. See also Owen in *Cyclop. of Anat. and Phys.* ii. p. 126, and Drummond in Charlesworth's *Mag. of Nat. Hist.* ii. p. 517–8.

[3] *Ann. des Sciences Nat.* n. s. vol. x. p. 34. And so of *Filaria medinensis* Rudolphi writes: "Filariæ nostræ prole quasi farctæ sunt; quod si harum longitudinem illius vero minutiem spectas, fœtuum multa millium millia singulis tribues."

[4] Kirby's *Bridgewater Treatise*, vol. i. p. 331.

Rudolphi confines himself to the proper parasites of animal bodies (*Entozoa*), which, following Zecler and Goeze, he divides into five orders:[1] 1. *Nematoidea*; 2. *Acanthocephala*; 3. *Trematoda*; 4. *Cestoidea*; and, 5. *Cystica*. In our exposition of their characters and genera, we shall reverse Rudolphi's plan, and begin with those of simplest organization.

ORDER I.—CYSTICA.

Character.—Body flattened or roundish, continued posteriorly into a vesicle peculiar to one or common to several individuals. Head furnished with two or four bothria,[2] or with four suckers, and a circle of hooked prickles, or with four prickly proboscides.[3]

Genus ECHINOCOCCUS.—An external simple or double vesicle, to the inner surface of which many entozoa adhere, like grains of sand. Of these the body is obovate, and the head armed with a circle of hooked prickles and suckers. The species infest the viscera of man, of apes, and of domestic cattle.

Genus CÆNURUS.—Vesicle simple, containing many adherent entozoa. Of these the body is elongate and flattish, rugose; the head armed with a prickly beak and with four suckers. The only known species (*C. cerebralis*, Plate DII. fig. 8) is found in the brain of domestic animals, especially of sheep, and it is the cause of a disease in them known by the name of the *sturdy*. It is curable by the judicious use of the trephine.

Genus CYSTICERCUS.—Plate DII. fig. 7.—External vesicle simple, containing a solitary entozoon, whose roundish or depressed body passes insensibly into a caudal vesicle. Head furnished with four suckers and a prickly beak. The species are found in quadrupeds, principally in their abdominal viscera. One occasionally makes good its habitat in the cellular substance between the muscles, and even in the eye and brain, of man; and the same is very common in the muscles of swine, whose flesh is then said to be *measled*. Blumenbach, as we have before mentioned, asserts that the wild swine are not subject to this disease; but the assertion seems unfounded. "In suis domestici cerebro et omnibus partibus musculosis vulgatissimus occurrit, neque *fero* deest." Rud. *Ent. Syn.* p. 180, c. p. 547.

Genus ANTHOCEPHALUS.—External vesicle hard and elastic, containing a more delicate one, within which there is a solitary entozoon. Body elongate, depressed, passing into a large caudal vesicle. Head armed with two or four bothria and four prickled rostella. This genus was previously named *Floriceps* by Cuvier, and naturalists in general have preferred that designation. The species seem to be almost peculiar to the fishes of southern climates, nestling in the abdominal membranes and viscera.[4]

The Cystica are all gemmiparous. In the *Cænurus*, the gemmæ pullulate from every part of the inner surface of the vesicle, where heads and their necks have been found at different stages of development, and always united together in groups. They appear at first like minute tubercles, having the limpidness of glass, and gradually evolve from this formless condition into their perfect state. Siebold has also traced the evolution of the young in the *Echinococcus*. The primary or maternal vesicle is lined with an extremely delicate epithelium, to which there adhere some limpid, mostly oblong, corpuscules, analogous to those primary buds met with in the neck of the Cænuri. The liquid of the vesicle contains some free Echinococci, within whose bodies, when their coronet of hooks and suckers is everted, nothing more is to be distinguished than some scattered limpid corpuscules. These Echinococci evidently derive their origin from the primary vesicle. On examining the inner surface of it, we notice here and there some minute vesicles, enclosing a mass of delicate granulations, whence the heads of the Echinococci pullulate, either solitary or in groups of from two to seven or more. In fact one portion of the granulous mass forms a small roundish body, which is manifestly continuous with the rest of the mass by one of its extremities. This rounded mass soon acquires insensibly a pear-shape, whence it passes to an oval, while at the same time its attachment to the mass whence it issued becomes more slender and frail. We now begin to discern, in the interior of this body, the circlet of hooked prickles and the limpid corpuscules; and now also the heads of the Echinococci commence to protrude and retract these parts, in doing which the entire body is alternately elongated and shortened. Arrived at this stage of development, the thin envelope that enclosed them is torn, but the young Echinococci do not immediately escape, for they are held to its inner surface by a slender cord proceeding from the envelope, and penetrating within their own bodies at a dimple indented in the posterior extremity. This dimple has nearly the appearance of a sphincter muscle grasping this cord of the envelope. After a short period the cords and the Echinococci separate. On being torn up, the envelope of the young Echinococci shrivels upon itself, the Echinococci are ejected, and in this manner they form a rounded mass, in the centre of which the shrivelled envelope is hidden, and upon which the worms repose, as the polypes do upon their stem. These masses sometimes remain for a space hanging from the inner surface of the maternal vesicle, and sometimes they are detached even before the Echinococci have themselves separated. The granulous mass contained in the vesicle is of the nature of a yolk, whence the heads derive the nourishment necessary for their development by means of the slender cords already mentioned. Siebold thinks it doubtful whether all the vesicles, large and small, that contain heads of Echinococci, and which float at freedom in the maternal vesicle among the freed heads, are detached from the inner surface of the vesicle, or whether some of them do not come direct from the freed heads, these having produced germs of Echinococci in their interior, and become distended by them into vesicles. Hanging from the free vesicles containing heads of Echinococci, he has often seen hooked spinules, which were perhaps the remains of a former circle of them; nay, he believes that he has even seen the remains of suckers in these vesicles. Still however there remains much obscurity on this strange transmutation; and even a greater darkness covers the origin and the propagation of the maternal vesicle. Since the *Echinococcus hominis* frequently presents us with small hydatids enclosed within each other after the manner of a nest of pill-boxes, we are forced to believe that the exterior hydatid is the primordial vesicle, within which the others have been successively evolved; but how? "I can no more answer this question," says Siebold, "than I can account for the existence of the primordial vesicle itself."[5]

---

[1] *Entozoorum Synopsis*, &c. Berolini, 1819, 8vo.

[2] Bothria are small pits or excavations, with a thickened rim, placed round or near the mouth.

[3] On this order the reader will consult with advantage Dr Hodgkin's *Lectures on Morbid Anatomy*, vol. i. p. 184–197.

[4] On this genus see some interesting observations by Dr Drummond in the *Magazine of Natural History*, n. s. vol. ii. p. 655, &c. and vol. iii. p. 227.

[5] See Burdach's *Traité de Physiologie*, vol. iii. p. 32–4. Paris, 1838.

ORDER II.—CESTOIDEA.

Character.—Body elongate, flattened, soft, continuous, or jointed. Head very rarely simply lipped, usually furnished with two or four bothria or suckers. Androgynous.

Genus Tænia.—Body elongate, flattened, jointed. Head with four suckers. The Tæniæ inhabit the alimentary canal, and principally the small intestines, but they have been found very rarely in the liver and gall-bladder. They occur only in vertebrated animals, some of them nourishing two or three species. Of those species which Rudolphi has described without a mark of doubt as to their reality, we find that one infests man, thirty-two the mammalia, sixty-five the birds, six the fishes, and two the reptiles. These numerous species he divides into two sections; first, those with an unarmed, and, secondly, those with a prickled head; but Mehlis has recently shown that many species which are furnished with hooked prickles when young, lose them when they arrive at maturity.

Genus Bothriocephalus.—Body elongate, flattened, jointed. Head subtetragonal, with two or four opposed bothria. Nearly allied to Tænia. Of twenty-four species described by Rudolphi, one is peculiar to man, three to aquatic birds, and twenty to fishes. The genus has been subdivided into several others by De Blainville. The individuals of one of these subgenera, *Dibothriorhynchus*, were affixed by the prickles of their probosces to masses of Ascarides, which again were the parasites of a butterfly.

Genus Triænophorus.—Body elongate, flattened, subarticulated. Mouth two-lipped, armed on each side with two tricuspidate spines. There is but one species, a native both of fresh and salt water fishes.

Genus Ligula.—In its state before evolution the body is flattened, continuous, very long, grooved down the middle with a furrow; and neither head nor genital organs are visible. In its developed state the body is also flattened, unjointed, and very long; the head armed on each side with a very simple bothrium; and ovaries are seen on the medial line in a single or double series, with threadlike filaments (*lemnisci*). The species are principally the intestinal parasites of birds; two or three kinds are found in fish; and one has occurred in the common seal.

Genus Tetrarhynchus.—Plate DII. fig 6.—Body flattened, unjointed. Head furnished with two bipartite bothria, and protruding four retractile prickly proboscides. The species are all piscivorous, although one has been also found in the stomach of a tortoise, and another in some cuttle-fish. They adhere to the abdominal viscera, to the gills and fins, and even infest the muscles. Bremser is of opinion that the species are Bothriocephali in an imperfect stage of development; and Nordmann believes this opinion to be correct, at least in regard to certain species. On the genus see Drummond in *Mag. Nat. Hist.* n. s. vol. ii. p. 571, &c.; and Leblond in *Ann. des Sc. Nat.* tom. vi. n. s. p. 293. The latter took a species from the interior of a fluke-worm or Distoma, a true entozoon, the parasite of another of not superior organization and scarcely of greater bulk. Helminthology is indeed full of miracles. *Lib. cit.* tom. vii. n. s. p. 249–253.

Genus Gymnorhynchus.—Body flattened, unjointed, very long, with a subglobular receptacle for the neck. Head furnished with two bipartite bothria, and emitting four naked retractile proboscides. Found immersed in the flesh of some giltheads (*Bramæ*) and rays or skates (*Raji*).

Genus Scolex.—Body flattened, unjointed. Head furnished with four bothria. The only species described (*S. polymorphus*) is common in the intestines of many fish and of the Cephalopods. There exists a suspicion that other Scoleces may be metamorphosed into Bothriocephali.

Genus Caryophyllæus.—Body flattened, unjointed. Head enlarged, scalloped, two-lipped, the lips superior and inferior. The species is common in the intestines of the carps (*Cyprinorum*).

In the preceding order there were no appropriated organs of digestion, which begin now to be developed. In the majority of the Tæniæ there are two or four canals which run through all the articulations of the long tape-like body, and which, underneath the cephalic knob, are connected together by numerous anastomoses, forming there a sort of net-work. It is remarkable that no one yet has succeeded in proving any direct communication to exist between these canals and the proboscis. In all the Tæniæ, the Bothriocephali, the Schistocephalus, and in the Triænophorus, the generative apparatus, both fecundating and reproductive, is multiplicate, while it is simple in Caryophyllæus. The orifices of both apparatus are, it seems, always separate. In *Tetrarhynchus epistocotyle*, Nordmann did not find any sexual organs; and the four retractile spinigerous proboscides led by four canals to as many oblong transparent muscular reservoirs, which, he conjectures, ought consequently to be considered stomachs. In the posterior part of the body of these animals, the same distinguished naturalist discovered a vascular system, composed of several longitudinal canals, and ramified by anastomoses; but no movement of any liquid could be perceived in it. On the posterior margin of the body there is a thick fringe of cilia, which is easily detached.

The eggs of the Cestoidea are multiform, and vary remarkably in size. According to Siebold, some have a single envelope, and others not fewer than three. The eggs of *Tænia stylosa*, when found in the intestines of *Corvus glandarius*, are quite peculiar in their structure; for they have four envelopes, of which the two external ones are round, the inner one oval, and that which lies between the second and the fourth is very narrow and drawn crosswise, having at the same time two very long twisted diverticula. The eggs of *Tænia cucumerina* deserve also to be particularized, from ten to twenty of them being always placed in a common envelope. The vesicle of Purkinje appears to be wanting in the eggs of the Cestoidea.

The embryo, while yet in the egg, is endowed with certain motions; and Dujardin discovered that the Tæniæ have then six hooked spinules, or horny falciform teeth, disposed symmetrically in pairs. These spinules have no relation, as one is at first disposed to conclude, with the spinules that arm the interior of the extrusile proboscis, or the circumference of the oval aperture; for they exist in the embryos of unarmed Tæniæ, as well as in those which are so provided; nor are the shape and disposition of the two kinds at all analogous.

The articulations of the body are not formed until some time after the embryo has quitted the envelope of the egg, but the first traces of the suckers surrounding the beak are sooner recognisable. It is probable that the little worm from the tench, described under the name of *Gryporhynchus pusillus* by Nordmann, is only the young of one of the Cestoidea, perhaps of a Tænia.

ORDER III.—TREMATODA.

Character.—Body flattened or roundish, soft, furnished with suctorial pores. Androgynous.

Genus Monostoma.—Body soft, roundish, or flattened. The sucker anterior and solitary. The Monostomæ live in the abdomen and intestines, and have been found in the muscles, of vertebrated animals. Of the species described in Rudolphi's *Synopsis*, one is from a mammal, nine from birds, ten from fishes, and three from reptiles.

Genus Amphistoma.—Body soft, roundish; an anterior and posterior pore or sucker. Of eighteen species, twelve belong to birds, three to the mammalia, and three to reptiles. The genus has been recently subdivided, or its definition will at least embrace the *Holostomum* of Nitzsch, the *Amphistoma* and *Diplodiscus* of Diesing; and the beautiful *Diplostomum* of Nordmann, found in the eyes of fishes, is nearly related.

Genus Distoma.—Body soft, flattened, or roundish. Suckers solitary, one anterior, the other ventral. A genus better known by the name of *Fasciola*. The species are the parasites of every order of vertebrated animals, and are exceedingly numerous, nearly 200 having been described. Of these, the most notorious is the *Fluke* (Plate DII. fig. 9), generally believed to be the cause of the *rot* in sheep, by which disease numerous flocks are annually destroyed. Another species (*Fasciola trachea*, Montagu in *Wern. Mem.* i. p. 197, pl. 7, fig. 4) breeds in the wind-pipe of poultry, and produces the fatal distemper usually termed the *gapes*.

The three preceding genera are the heads of a large family, extremely variable in the degree of organization, but, amid this diversity, always marked by having from *one* to *three* suckers of more or less perfect formation. It is from the number, the form, and the position of these organs that attempts have anew been made to subdivide the family into groups and genera; for many new and extraordinary forms have been discovered since the publication of Rudolphi's work. Our space forbids us to characterize these novelties, but we may mention the *Gregarina* of Dufour, living in groups in the alimentary canal of tardigrade insects; the *Diplostomum*, which peoples the humours of the eyes of fish; the *Cercaria* of fluviatile mollusca, so remarkable for its anomalous mode of propagation; and the *Diplozoon*, the only animal known which is truly double, having two heads and two bodies united at their middle, and in organic connection, and, unlike the Siamese twin, no monstrous production, but a normal species after its kind.[1]

Some of the species in the family are without sex, and seem to be composed of granules lying in a fluid gelatinous matrix, held together by a thin skin, which gives the animal form and consistency. On the contrary, in the greater number of the species there is a digestive apparatus, consisting of a mouth, an œsophagus or pharynx, and an intestine forked or sometimes ramified; but there is no anus, for the ascription of this name to the posterior sucker is founded in error. In several genera we find subservient to the digestive organs a double system of vessels, one closed, the other (furnished with a reservoir, named by some helminthologists the *cisterna chyli*) has a communication with the exterior by means of a caudal aperture, the vent of some secretion. These more complex species are all hermaphrodites, some fecundating themselves, while others copulate after the fashion of the snail. The sexual organs are often very complicated and much interwoven, but they have distinct orifices. The eggs are diversiform, and usually laid anterior to the formation of the embryo. There are some exceptions, however, and at least one species of Monostoma is viviparous. When the embryo is matured, the upper part of the shell of the egg bursts and opens like an operculum, allowing the embryo to pass out; and then it swims about vivaciously in the circumfluent medium by means of cilia that cover the body. We know not what may be the number and the nature of the metamorphoses through which the young passes before assuming the shape of the parent. The young of the *Monostoma mutabile*, observed by Siebold, contained all of them a worm of a peculiar figure, having no correspondency with the figure of the mother, but resembling the cyst of some Cercariæ. Analogy induces Nordmann to believe that this worm within the young is in fact changed into a cyst, from which, under favouring circumstances, the Monostoma is ultimately developed.[2]

Genus TRISTOMA.—*Capsala* of *Bosc.*—Body flattened; two simple suckers in front and a radiated one behind; the mouth emitting a proboscis? between the former. The species infests the gills of various fish. It is occasionally found at freedom in the sea, and has occurred on the British coast.

Genus PENTASTOMA.—Body roundish or flattened; mouth protruding a little hook, placed between the anterior suckers, of which there are two on each side, arranged in a lunated manner. Parasites of the viscera of the quadrupeds. The best-known species is found in the frontal sinus of the dog and of the horse, growing to the length of six inches. The sexes are distinct. The name *Linguatula* has been preferred for the genus, of which Diesing has published a monograph, with descriptions of eleven species. Because the sexes are separate, Cuvier gives it a place among the Nematoidea, while Diesing thinks its peculiar structure entitles it to be reckoned the type of a separate order, which he names *Acanthotheca*; and Miram expresses an opinion the same as Diesing. *Recherches sur l'Anatome du Pentastoma Tœnioides*, in *Ann. des Sc. Nat.* n. s. tom. vi. p. 135. (Plate DII. fig. 5.)

Genus POLYSTOMA.—Plate DII. fig. 10, 11.—Body roundish or flattened; six suckers in front, a ventral and posterior one solitary. This genus is the type of a family named *Polycotyla* by Blainville. It contains many genera, and among them the Tristoma, and others which have often been classified with the Leeches. The bulk of the species prefer the exterior of animals, especially the gills of fish, to which they adhere by means of the prehensile organs or suckers on the hinder part of the body. All of them are hermaphrodites. The orifices of the genital organs are in front, not far from the mouth. On each side of this there is an oblong or round sucker; in the œsophagus a body resembling a tongue has been distinguished; the alimentary canal is dendritic, without an anus, and all the body is permeated with a double vascular thread, in which there is obviously a circulation of blood, attended with a vibratile motion. Some species are furnished with eyes, or eye-like specks; and the surface of the body is variegated with spots, or tinctured of a deep colour.

Intestinal Worms.

ORDER IV.—ACANTHOCEPHALA.

Character.—Body roundish, utricular, elastic; proboscis retractile, armed with spinules arranged in rows; sexes separate.

Genus ECHINORHYNCHUS.—The only genus of its order, but a very numerous one, for not less than 100 species have been discriminated. They are found in the intestines and other viscera of vertebrated animals, retaining themselves in their position by means of the prickly proboscis,[3] which is not the organ for taking their food, for its extremity is not perforated. The sexual organs are very complex. The ovaries are not attached, but float free in the cavity of the sac-like body. The ova resemble spicula, and appear to be discharged posteriorly through a minute pore.[4] It seems that the species undergo a considerable change in figure in their progress from the embryo to the adult state; and some lose the prickles of their proboscis.

ORDER V.—NEMATOIDEA.

Character.—Body cylindrical, elastic, the intestinal tube terminated at one end by the mouth, at the other by an anus; sexes separate.

Genus LIORHYNCHUS.—Body elastic, round; head evalvular; mouth with a smooth protrusile tube. Of the three species mentioned in Rudolphi, one infests the badger, one the seal, and one the conger eel. Diesing has lately characterised several allied genera.

Genus OPHIOSTOMA.—Body round, elastic, attenuated towards each extremity; head with an inferior and superior lip. The *Fissula* of Lamarck. The species are intestinal, and occur in quadrupeds and fishes, occupying the swimming bladder of the latter.

It is probably in the neighbourhood of Ophiostoma that we should place the genus TETRASTOMA of E. Forbes, a strange parasite, "fixing itself by means of four suckers or mouths to the walls of the stomach, and of the vessels of the Cydippe, after interrupting the circulation of the fluids." Mr Forbes first described it as a tongue-shaped organ existing in the stomach of the crystalline medusans, but its parasitical nature was discovered by Major Playfair of St Andrews. See *Athenæum*, Sept. 26, 1840, p. 746.

Genus ASCARIS.—Body round, elastic, attenuated at both extremities; head trivalvular; spiculum of the male double. The species are numerous, and difficult of discrimination. The most common example of the genus is *A. lumbricoides*, found in the small intestines of man, of the swine, of the ox, horse, and ass. See Plate DII. fig. 3.

Genus STRONGYLUS.—Body round, elastic, attenuated at both ends; mouth circular or angulated; apex of the tail in the male terminated with a purse-like sheath, whence the penis is protruded.

The *S. gigas* (Plate DII. fig. 4) may be considered the type of the genus. It attains the length sometimes of two or three feet, and is as thick then as a man's little finger; and it makes one shudder to think that this monstrous worm is occasionally the cankerous inhabitant of the kidneys of man, where it lies rolled up, battening on their flesh, and producing unspeakable torture. It afflicts other animals, as the dog and wolf, and is not confined to the kidneys. It is often found of a deep red colour, dependent undoubtedly on the blood it has sucked from its victims. Of worms excreted with the urine, see cases very interesting to the "greedy hunters after monsters," in Le Clerc's *History*, p. 264 et seq. Also the *Cyclopædia of Practical Medicine*, vol. iv. p. 516.

---

[1] The *Syngamus trachealis* has been adduced as another example, in which the male is organically blended by its caudal extremity with the female; but Siebold afterwards discovered that he had been deceived in this description. Lam. *Anim. sans Vert.* 2de edit. iii. p. 652.

[2] Lamarck, *Anim. sans Vert.* vol. iii. p. 617, 2de edit.

[3] Of this organ Dr Drummond has given a good description in *Mag. Nat. Hist.* n. s. ii. p. 520; and some most interesting observations on the economy in vol. iii. p. 63–71.

[4] See Drummond in *loc. cit.* p. 523.

Genus Physaloptera.—Body round, elastic, attenuated at both extremities; mouth circular; tail of the male deflexed, winged on each side, ending in an inferior vesicle; penis protruded from a tubercle. The species are few and intestinal.

Genus Spiroptera.—Body round, elastic, attenuated at both extremities; mouth circular; penis emerging from between the wings of the spirally involute tail. The species are numerous. One has been said to occur in the urinary bladder of man.

Genus Cucullanus.—Body round, elastic, attenuated behind; mouth circular, placed under a striated hood; the male organ a double spiculum. The species infest the stomach and intestines of various fish.

Genus Oxyuris.—Body round, elastic, the posterior part of the female subulate; mouth circular; penis sheathed. The species are few, and confined to quadrupeds. One is very troublesome to the horse; and the worm which perhaps annoys man more than any other (*Ascaris vermicularis*) has lately been removed to this genus.

Genus Tricocephalus.—Body round, elastic, the anterior capillary extremity suddenly succeeded by a thicker portion; mouth circular; male organ simple and sheathed. "The species inhabit the large intestines, particularly the cœcum of the mammalia; they do not occur in either birds or fish."—Bellingham. The *T. dispar* (Plate DII. fig. 2) is said by Rudolphi to be very common in the large intestines of man. "It is about two inches in length, only one third of which is taken up by the thick part of the animal. This portion has a spiral form in the male, which is furnished with a small penis, protruding from near the tail. In the female, which is oviparous, the thick portion is straighter, and is simply pierced at the extremity. On the continent it would seem that this is the worm which is met with the most frequently in the human intestines. Indeed some of the most distinguished helminthologists state that they scarcely ever fail to find them. The large intestines are their principal seat, but more especially the appendix vermiformis of the cœcum. Though I have frequently and carefully sought for this worm, I have only once been able to find it. In this instance it was lodged in the mucus filling the appendix of an emaciated and cachetic girl, who had been much exposed to want and hardship." Dr Hodgkin's *Lectures*, &c. vol. i. p. 207. Dr Bellingham's experience is very different; he finds it very commonly in the Irish. See his Catalogue of the Entozoa indigenous to Ireland, in the *Mag. of Nat. Hist.* n. s. vol. iv. p 343, &c.

Genus Trichosoma.—Body round, elastic, very slender, growing insensibly larger to the posterior extremity; mouth a mere point; male organ a simple sheathed thread. Named *Capillaria* by Zeder. The species are found principally in birds, next in the mammalia, and very rarely in reptiles and fish.

Genus Filaria.—Body round, elastic, linear, elongate; mouth circular; male organ a simple spiculum. The species are numerous, and infest many avertebrated[1] as well as vertebrated animals. They are principally intestinal, but a species has been found in the eye of the horse, another in the eye of man, and another in the bronchial glands. The most celebrated species (*F. medinensis*, or *Guinea-worm*, Plate DII. fig. 1) burrows in the cellular tissue under the skin. It was well known to the ancients; and a portion of the history of it given by Paulus Ægineta may be quoted: "In India and the countries above Egypt, there are bred little dragons, animals like worms, in the muscular parts, as the arms, thighs, and legs, and in children they are in the sides, and plainly move under the skin. But after some time a place nigh the end of the worm suppurates, the skin breaks, and the head of the little dragon comes out. While it is drawn out it causes pains, and especially when it is broke. Wherefore some say that a leaden weight should be hung to the dragon, that the falling out should not be in heaps, but in pieces. Others condemning these, because by the weight of the lead the worm is broken, and causes cruel pains, order the part to be put in warm water, by the fomentation of which the worm comes out, and is drawn out piecemeal by the fingers." Le Clerc's *Hist. of Worms*, p. 242. Freind's *Hist. of Physick*, vol. i. p. 49, &c. Mr Hutcheson gives an account of his having extracted one that measured three yards and a half in length. Good's *Study of Medicine*, vol. vi. p. 653.[2]

The eggs of the Nematoidea, with a very few exceptions, are of an oval shape when mature. The changes which they undergo in the process of hatching have been minutely described by Siebold, but we can only mention one or two particulars. The covering or shell is colourless and single, but frequently double. The vitelline mass is whitish, and contains, in unripened eggs, a well-marked proligerous vesicle with a proligerous spot. When these immature eggs have passed into the uterus, remarkable changes begin in the yolk, which at this period is a mass of delicate granulations, set in a uniform manner, and completely filling the envelope of the egg. The proligerous vesicle, deeply hidden in the vitelline mass, is obscurely seen, and soon afterwards disappears. On its disappearance, the physiologist is surprised to observe on the vitelline mass those remarkable grooves, the existence of which he had never suspected in any invertebrated animal, and least of all in the Entozoa, and which had been seen only in the eggs of the Frogs (*Bactracians*) by Prevost and Dumas, and some other observers.[3]

The *Intestinaux* constitute the second class of zoophytes in Cuvier's arrangement.[4] He divides them into two orders, so different in their organization, that they seem rather to deserve the rank of classes. The first order, the *Intestinaux cavitaires*, have an alimentary canal floating in a distinct abdominal cavity, with a mouth and an anus; but the body of the constituents of the second order, the *Int. parenchymateux*, contains within its parenchyma only ill-defined viscera, having the resemblance mostly of vascular ramifications; and sometimes even these traces of organism are imperceptible. We shall here present a brief sketch of Baron Cuvier's system.

ORDER I.—THE CAVITAIRES, *Cuv.*

This nearly corresponds with the order Nematoidea of Rudolphi, embracing also the genus Linguatula or Pentastoma, and the Prionoderma, which Rudolphi has placed among his fictitious or obscure species. Cuvier believes that at the end of this order we ought to classify, as a distinct family, the Lernææ of Linnæus, or Epizoaires of Lamarck; but it is now proved that these are really crustaceans, which, in their infancy, do not differ from the new-born Cyclopes, and are equally capable of swimming about; but assuming the character of adhesive parasites, they suffer a deformity that increases with their growth, and conceals their nobler alliances,[5] for they never acquire all the members with which the more normal crustaceans are provided. Of all the paradoxical creatures which the naturalist meets with in his researches, there is none that surpasses or equals these in eccentricity, none more at variance with our notions of animal conformation, and exhibiting less of that decent proportion between a body and its members, which constitutes what we choose to call symmetry or beauty. Of these monsters we shall attempt no description; but the figures of a few of them, given in Plate DII. figs. 13–17, will convey some idea of their shapes and variety. They are all external parasites, living on the skin and on the gills of fish, to which they adhere by hooked grasps or claws; and it is presumed that they injure the fish by sucking out their blood. Burmeister, who places them among the Siphonostomous Crustacea of Latreille, gives the following synopsis of their genera.

I. Family Penellina.

BODY WITHOUT TENTACULA OR ARTICULATED MEMBERS.

* Body more or less twisted in an angular manner, unequally thick, and furnished anteriorly with bifurcated arms.
  † Three long corneous arms placed around the mouth; the two anterior, or all the three, forked: the oviferous sac resembling a spirally twisted cord. Lernæa, *Oken*.
  †† Four soft and fleshy appendages placed around the mouth; the anterior forked; oviferous sac cylindrical. Lerneocera, *Blainv.*

---

[1] On the Entozoa of insects consult Léon Dufour, in *Ann. des Sc. Nat.* n. s. tom. vii. p. 5.

[2] Its exterior figure might induce us to place after Filaria the genus Trichina of Owen, found in myriads in the voluntary muscles of man, but its simplicity of structure scarcely raises it from among the Infusoria, more especially from above the eels of vinegar and paste. On this interesting worm, see the elaborate essay of Owen in *Trans. of the Zoological Society*, vol. i. p. 315; and in *Cyclop. of Anat. and Physiology*, ii. p. 114; Hodgkin's *Lectures*, vol. i. p. 211; and several essays in recent volumes of the *Lancet* and *Medical Gazette*.

[3] See Burdach's *Traité de Physiologie*, vol. iii. p. 59–64.

[4] *Règne Animal*, iii. p. 245–274.

[5] The males however retain their freedom and powers of locomotion at all ages. See Cuvier, *Règ. Anim.* iii. p. 255, note 2; and Burdach's *Traité de Physiologie*, tom. iii. p. 130.

- ** Body straight and of equal thickness; four pairs of cutaneous prominences toward the anterior part, which is prolonged into the form of a neck.
  - † Without arms; nor is the tail penniform. PENNICULA, *Nordm.*
  - †† With arms, and a penniform tail. PENELLA, *Oken.*

II. Family LERNÆODA.

BODY WITH TWO PINCERS, OR PREHENSILE APPENDAGES, SITUATED BEHIND THE PROBOSCIS, AND WITHOUT SWIMMING FEET, WHICH ARE SOMETIMES REPRESENTED BY SIMPLE CUTANEOUS PROLONGATIONS.

- * Prehensile apparatus simple, situated at the point of union between the trunk and the neck. ANCHORELLA, *Nordm.*
- ** Prehensile apparatus elongated, composed of appendages which have the shape of arms, and which are united together near their extremity.
  - † Cephalothorax prolonged into a neck.
    - § Pincers with hooklets placed on the lower part of the neck, between the arms. TRACHELIASTE, *Nordm.* LERNANTOMA, *Blainv.*
    - §§ Pincers with hooklets placed at the upper part of the neck, almost behind the head. BRANCHIELLA, *Nordm.*
  - †† Cephalothorax short, rounded or heart-shaped; pincers, with hooklets, placed immediately in front of the arms.
    - § Arms very long and thin: the abdomen elongated, and not jointed. LERNEOPODA, *Blainv.*
    - §§ Arms very long and thin: the abdomen circular and jointed. ACHTHERE, *Nordm.*
    - §§§ Arms short and thick: abdomen not jointed, and verrucose. BASANISTE, *Nordm.*
- *** No prehensile organs in the shape of arms.
  - † Tentacula of two or three joints not formed of articulated feet, armed with hooklets; a pair of jaws and two palpi. CHONDROCANTHUS, *Cuv.*
  - †† Tentacula with six joints; an eye on the top of the head; three pairs of jointed pincers behind the mouth, which is conical. LERNANTHROPE, *Blainv.*

After this family there follow, in the system of Cuvier, some genera of marine worms, which are not parasitical, and are undoubtedly members of the family Planariæ. The NEMERTES had been previously characterized by Sowerby, and by him named LINEUS. It is remarkable for the extraordinary length to which it grows. We have been informed that specimens of thirty feet long have been seen, and have had some in our possession which, when extended, could not be less than fifteen or twenty. It is to be found under stones, coiled up in an intricate mass of a purplish-brown or claret colour, smooth and glossy, of nearly uniform calibre throughout, and free of wrinkles or joints. The head is distinct enough; and underneath it there is a long slit, which is the mouth. The intestine runs the entire length of the body; and, what is very curious, we have a specimen which has swallowed a periwinkle, the shell forming a knob near the middle of the body, reminding us of the appearance of a gorged snake. After the Nemertes, says Cuvier, we ought probably to place the TUBULARIÆ of Renieri, which are equally large and very much elongated, but which have a small mouth pierced under the anterior extremity; and the OPHIOCEPHALES of Quoy and Gaimard, distinguished by having the apex of the snout cleft; and the CEREBRATULES of Renieri, which differ from these merely in the comparative shortness of the body.

ORDER II.—THE PARENCHYMATEUX, *Cuv.*

This order is divided into four families. The first is co-equal with the *Acamnocephala* of Rudolphi; the second embraces the *Trematoda* of the same author, with some additions. One of the most extraordinary is the HECTOCOTYLES of Cuvier, a long worm, compressed and enlarged at the anterior extremity, upon which is the mouth, whose inferior surface is garnished with numerous suckers, arranged in pairs; and at the posterior extremity there is a sac, filled with folds of the oviduct. One species, which hides itself in the flesh of the sea-polypus (*Octopus*), is four or five inch-es long, and has 104 suckers; another of smaller size, and with seventy suckers, is the parasite of the *Argonauta*. The ASPIDOGASTER of Baer is a minute parasite of the mussel, distinguished by having under the belly a lamina, hollowed with four rows of little pits. In this family also Cuvier arranged a multitude of animals which were formerly comprised in the genus PLANARIA of Müller.[1] They are little worm or leech-like animals, with a soft, compressed, or foliaceous body, found both in the sea and in fresh waters. There is no abdominal cavity. The mouth, placed in the belly near its middle, is furnished, in many, with a protrusile proboscis, which leads into an intestine of a dendritic character, and whose ramifications permeate the whole body. A vascular network occupies the sides; and there is, posterior to the oral aperture, a double system of generative organs. The species are androgynous like the snails, and oviparous. The head is ornamented in most with black specks, which are probably eyes. They are voracious creatures, feeding on animal matter; but, above all, they are remarkable for the facility with which they reproduce any part of the body that may have been lost by accident, or cut away by the curious experimenter. In this wonderful power they equal the Hydra. The species and races are extremely numerous, and admit of much complicated classification.[2] Dugès distinguishes them into the typical *Planariæ*, with a ventral aperture; the *Prostomæ*, which have one orifice at the anterior, and another at the posterior extremity; and the *Derostomes*, in which the oral aperture is beneath, but placed considerably forwards.[3]

Echinodermata.

The third family of the intestinal Parenchymateux is named the TÆNIOIDES. It conjoins the orders Cestoidea and Cystica of Rudolphi. The fourth family is the CESTOIDES, and embraces only the genus *Ligula* of Bloch, parasitical worms found in the intestines of some birds, and of various fresh-water fish. They appear the simplest of all the Entozoa. The body is like a long ribbon, obtuse in front, marked with a longitudinal stria, and finely scored crosswise. There is apparently no external organ; and in the interior we see nothing but the ova scattered in the parenchyma. The species which infests the bream grows to five feet in length; and Cuvier says that the worms are considered in some parts of Italy an agreeable food.

In the bowels of some seals, and birds which live upon fish, there are found certain worms very like the Ligulæ, but in which genital organs have been developed, and even a head similar to that of the Bothryocephalus or tape-worm. Rudolphi hazards the conjecture that these worms of birds are identical with the Ligulæ of the fish, which have acquired their fuller organization by passing from the intestines of the cold-blooded animal into those of a warm-blooded one. There are some facts in the history of other tape-worms which give a colour to this conjecture: and we may just call attention to its bearing upon the question of their equivocal generation.[4]

II.—ECHINODERMATA.[5]

The Echinodermata have been defined to be radiated animals, with a coriaceous or crustaceous skin, commonly tuberculated, or even spiny, and perforated with holes arranged in regular series, whence issue contractile tentacular suckers. The mouth is either inferior or lateral, and mostly armed with certain osseous pieces that form a circle of teeth within the lip; the stomach is a loose bag, with distinct parietes, and with an intestine or cœcal appendages; the respiratory apparatus is vascular; and the species are oviparous. This definition however must not be too nicely examined, otherwise several animals, which offer but a feeble and partial adumbration of its characters, might be excluded from a class to which they properly belong. The stellated disposition of the organs is generally so remarkable, that fancy will dream the Echinodermata to be the children of night, which have drawn their figures from the stars that presided over their birth; but there are among

---

[1] The best history of the Planariæ is entitled *Observations on some interesting Phenomena in Animal Physiology, exhibited by several species of Planariæ.* By John Graham Dalyell, Esq. Edinb. 1814, 8vo. Judging from the infrequency with which this interesting volume is quoted, we presume it to be much less known than it deserves to be.

[2] They constitute the class TURBELLARIA of Ehrenberg, and a synopsis of his arrangement is given in Lam. *Anim. sans Vert.* 2de edit. vol. iii. p. 609.

[3] See a description of some British species by Dr Johnston in the *Magazine of Zoology and Botany*, vol. i. p. 529.

[5] From ἐχῖνος, *a hedgehog*, and δέρμα, *the skin.* Synonymes: Echinoderma; Les Echinodermes; Cirrhodermaires; Crustacea of Blumenbach.

them some vermiform families which have resisted the planetary influence, excepting only in certain parts around the mouth. Their next most general character is derived from the tentacular tubes which the animals push out from pores drilled in rows between the vertical segments of the thick integument of the body, and withdraw again in part at pleasure: but the character becomes abnormal in some Holothuridæ, which have these suckers pullulating irregularly from the surface; and it fails us altogether in Sipunculus and its allies. The organs in question much resemble the tentacula of the snail, but they are really very dissimilar both in the use and mechanism of their movements: they may be compared to the glass of a thermometer, for they are closed tubes, with a vesicular bulb placed within the body, and they are protruded by forcing the fluid, with which the bulb is filled, up the cylindrical portion. It is not through them, as Lamarck imagined, that the circumfluent water gains access within the body, although it is very true that almost all the Echinodermata contain a large but variable quantity of it, partly flowing through a special apparatus, and partly effused, if we may so speak, into the visceral cavity, bathing the surface of every viscus which may be said to float in it; and since the quantity of this water can be increased or lessened at pleasure, so we find that the contour of all the flexible species is liable to alteration of figure, according to circumstances. When

> Batt'ning in ease, and slumb'ring life away,

the skin is rotund and swollen, and the organs are distended and displayed; but if alarmed or removed from their sites, the fluid escapes from them, and collapsion and retraction follows. Other purposes which this water must serve, are its aid in rendering the crude nutritive fluids of digestion fit for assimilation, and its purifying influence over the blood; for we learn from Delle Chiaje, that in all the Echinodermata there is a blood of a yellowish or orange colour, composed of a large proportion of lymph, and a certain number of globules endowed with a self-rotatory motion.[1] In what course this blood circulates, has not been determined. Tiedemann, who may be regarded as our best authority on such a point, says that it "moves in a circle, but which is confined to the alimentary sac and ovaria alone. In the Asterias, numerous thin-coated veins, coming from the stomach, the cœcal appendages, and ovaries, unite into a single trunk. This produces a dilatation analogous to a heart, and then ramifies like an artery. In sea-hedgehogs are found, on both sides of the circumvolutions of the intestinal canal, two vascular trunks, the external of which seems to be a vein, and the internal an artery. These two trunks communicate by a dilatation similar to a heart, or by their minutest ramifications. The intestinal canal of Holothuria likewise exhibits an arterial and venous trunk, connected with each other by their smallest ramifications, as well as by a large vascular net-work spread over one branch of the respiratory organ."[2] Delle Chiaje's description of the same system differs considerably;[3] and it is difficult to define the limits between it and the system of vessels for conveying currents of water through the body. Blainville, of distinguished excellence as a comparative anatomist, felt this difficulty. He has concluded that there is no real circulation, and that the sanguineous system of the Asterias, and perhaps even of the Echinides, is nothing else than a system of ramose aqueducts, like the tracheæ of insects; and indeed it appears certain that these vessels communicate with the exterior by orifices more or less conspicuous. But, he adds, it is difficult to say as much of the vessels which we find in the Holothuridæ, for no anatomist has suspected their direct communication either with the arbuscular tentacula, or with the real aquiferous vessels, or with the desidroidal branchiæ; so that in these animals there may be an oscillatory movement of the blood in its special system, but certainly no circulation of it, returning and going to and from a font of pulsion.[4]

The aquiferous system alluded to must not be confounded with the aquiferous cutaneous tubes that jut out from between the tubercles on the dorsal surface of the star-fishes, but is an internal ramose set of vessels for leading water from the general cavity of the viscera, more especially into the locomotive organs of the animal, and its buccal tentacula. "It is composed of vessels," says Tiedemann, "which commence from a canal placed around the mouth, and spread in rays over the internal surface of the skin, as in Holothuria, or proceed to the chalky covering, as in sea-hedgehogs and asterias. These vessels open in the hollow tentacula,[5] and their vesicular dilatations. They contain a limpid fluid, which is shed over the tentacula during the animal's motions, and causes their increase or shrinking. When the animal draws in his tentacula, the contraction of their muscular coats forces the liquid again into the vessels. The fluid contained in this vascular system is not therefore agitated by a circular movement, but only flows outwards from within, and *vice versa*. This liquid, which is probably derived from the blood, seems at the same time to serve for the nutrition of the skin, of the chalky covering, and the locomotive organs."[6]

With this system, that of respiration is most intimately associated; nor indeed are there any separated branchiæ, either in the star-fish or sea-eggs, whose fluids are aerated by a flow of pure water over their surfaces, and around and within their viscera, driven over them in currents determined by the regulated action of vibratile cilia, which clothe them almost everywhere, as the researches of Dr Sharpey have more especially proved.[7] In the Holothuridæ, anatomists have generally considered as pulmonic certain organs which lie between the long curves of the intestine, and closely connected with it. They are very much branched in a dendroidal fashion in some species, their branches reuniting successively backwards, until they form at last two trunks, or one only, that opens with the intestine into the cloacum; but it seems to shew how readily their presumed function can be transferred to the general cavities, when we find other species of the family in which these organs are slightly sketched, and some in which their existence is not to be demonstrated.

With Lamarck, we shall further pursue the history of this class under its three sections or orders, which are named and defined as follows.

I. FISTULIDES. Body elongate, cylindraceous; the skin leathery, soft, and irritable; intestine with an oral and anal orifice, the former encircled with retractile tentacula.

II. ECHINIDES. Body more or less rotund or angular, covered with a shell of immoveable testaceous pieces without projecting arms; anus distinct from the mouth.

III. STELLERIDES. Body depressed, circular or angulated, and divided into arms or rays; the skin creto-coriaceous, tubercular; intestine in some families only, with an orifice distinct from the mouth.

---

[1] Blainville's *Man. d'Actinologie*, p. 65.

[2] *Treat. on Comp. Physiology*, trans. i. p. 160.

[3] The differences are fully pointed out by Dr Sharpey in his excellent article "Echinodermata," in the *Cyclop. of Anat. and Physiology*, ii. p. 41.

[4] *Man. d'Actinologie*, p. 86.

[5] The feet or suckers are here meant.

[6] *Comp. Physiology*, trans. vol. i. p. 161. Dr Sharpey doubts their being nutritious vessels, as is here asserted, for their liquid is not sanguineous, or even a secretion, "but agrees almost entirely in composition with sea-water." *Cyclop. of Anat. and Phys.* ii. p. 41.

[7] *Cyclop. of Anat. and Phys.* art. "Cilia," i. p. 615.

ORDER I.—FISTULIDES,[1] Lamarck.

The radiant character of the class is faintly impressed upon this family, being marked with decision only in those parts which encircle the mouth. The form of the body is in general that of an elongated cylinder or pentagon, rather unseemly, and invested with a thick coriaceous tunic, which is sometimes scaly, like the skin of a fish, more frequently of a uniform earthy colour, or white painted with bright red or orange spots. If placed in a vessel of sea-water, we soon observe, issuing from perforations in the skin, a number of papillary tubes, which the animal has the power of extending at will. These are scattered over the body, or more usually arranged in rows, limited sometimes in extent, at other times running uninterruptedly from one extremity to the other. The creature gives perhaps little other evidence of life than what we infer from the protrusion of these organs, and from continual changes in the figure of its body. A species of Holothuria, which we watched for some time, was as changeable in this particular as its native ocean. From a long vermiform cylinder, it would become gradually shortened, and swollen in the centre; then it would relax itself, and again become cylindrical; next one part would be blown out, and another drawn in, with a deep stricture, as if a thread had been tied round; or the contraction would begin near the head, which is then made very narrow, and would spread backwards, the anterior portion recovering its original diameter as the wave of constriction passed away; and sometimes the contraction will spread in the opposite direction. This mutability in form is dependent on the action of the muscles which enter into the composition of the skin, and which are of two kinds: one set forms a series of transverse parallel fibres, lining its inner surface completely with an even muscular coat, while the other set is collected into five or ten strong cord-like tendinous bands, which stretch from the oral to the anal aperture, usually in pairs, but where five only, they are at equal distances.

In this state, it is not always easy to say which is the anterior and which the posterior extremity, for the tentacula and foreskin containing the oral apparatus are retractile, and then wholly concealed. When displayed, the tentacula form a circle, in which all the beauty of the creature centres. They are all alike in some species; in others two of them are smaller and less divided than the rest, which for the most part are sufficiently branched to be called plumose or arborescent. Whether their functions are the same, has not been questioned; but we may observe, that the less are often alternately pushed out and in when the larger are kept steadily extended. They fringe, and are the continuation of a ligamentous neck; and in their middle we find the mouth, a round aperture, often limited by an interior ring of bony pieces, bound together by a strong muscular ligament, and giving insertion to one half of the longitudinal muscles. The pieces of the ring are ten in number, a large one placed in regular alternation with a smaller, all of them of a fibro-cretaceous consistence, so that, acted upon by the muscles attached to them, they must prove bruising instruments of considerable power.[2] Exterior to, and between them, there is a circle of five or more vesicular glands of a linear oblong shape and fleshy nature, the use of which is undetermined; for while Bohadsch and Cuvier regard them in the light of salivary glands, Blainville is tempted to refer them rather to the aquiferous system. The intestine is very long. The superior portion, or that immediately under the osseous ring, from being thicker in texture and a little wider, may be considered the proper stomach, for the remainder is of a cylindrical form and nearly equal calibre throughout. It is tied to the side by a vascular mesentery; and after making a large bend upon itself within the belly, terminates in a cloacum or passage common to it and the respiratory apparatus, and which leads outwards by an aperture opposite the mouth. The only chylopoetic organ attached to the intestine, the salivary glands excepted, is what is presumed to be a liver, under the guise of some penicillate structures, which occupy the space formed by the sinous bend just mentioned. From this structure, and from the great length of the alimentary canal, we may infer with probability that the food of the Fistulides is of sparingly nutritious quality, while their organization otherwise fits them to be little better than the recipients of that chance fare which currents or accident may bring almost within contact. Bohadsch found the intestine of a large Holothuria, of which he has written an excellent description, filled with sea-sand and the fragments of corallines and fuci;[3] and from matter like this, and the water gulped with it, the necessary nourishment is extracted during its long and lingering course.

The ovaries consist of a bundle of filaments attached to a determinate spot on the side near the middle of the visceral cavity, and notwithstanding their numbers, they have only a single exterior orifice placed in the median line near the head, which it is often difficult to discover from its minuteness. Each ovary contains many ova, of a roundish figure, and apparently immotive, being unclothed with the cilia which move about the eggs of polypes. At the period of their maturation, there occurs a simultaneous development of certain very extensible filaments, which originate from near the anus, and are supposed by some anatomists to be the male organs. How and under what form the ova escape, is not known. They are occasionally retained in the abdomen and developed there, which has given rise to a belief in their viviparous generation. Thus Bosc affirms, on the evidence of personal observation, that the common species of Holothuria are viviparous;[4] and the same assertion had been made long before by Otho Fabricius in regard to his H. pentactes.[5] But the most singular notion has been broached, that these animals do, at their full time, evacuate the entire mass of pregnant ovaries, with the other viscera, through the mouth or anus; do, in fact, voluntarily, and from a law of their nature, eviscerate themselves.[6] The fact on which this seemingly absurd conjecture is based is most singular, perhaps unexampled in any other animals. When a Holothuria is placed in a basin of sea-water, it has been seen to emit jets of water from the posterior aperture at regular intervals, the jets succeeding each other at not more than about a minute's interval. This water is undoubtedly what has been rendered injurious by its stay and use in respiration, mixed probably with a considerable proportion from the intestine. But when the water in the basin has become impure, these jets become also less regular; and after evidence of uneasiness, and some unusual motions, the worm will at length vomit up its tentacula, its oral apparatus, its intestine entire and with its appendages, and a large cluster, if not the whole, of the ovaries. And after this complete embowelling, the animal lives for at least six or seven hours; for the empty skin shews, by its motions, that nearly all its irritability remains, and even its power of locomotion is not lost. "Denique, quod magis mirum est, omnia *Hydræ* individua, postquam intestina sua dejecere, septem et ultra horas supervivunt, motu non duntaxat elastico, sed progressivo gaudentia.[1]" Sir John G. Dalyell has even proved, by actual experiment, that if this poor embowelled worm is supplied with fresh sea-water at proper intervals, it will live to replace all its viscera with new growths, reproduce new tentacula, new teeth, a new stomach and intestine, and all its complicated aquiferous system, so as to be in every respect as it was previous to its wonderful evomition. It is by such miracles that we are brought to exclaim with Pliny, "mihi contuenti sese persuasit rerum natura, nihil incredibile existimare de ea."

The Fistulides are natives of every sea. Blainville believes them to be more numerous on the coasts of cold or temperate countries, than under or within the tropics; but the data for such an opinion are unsatisfactory.[2] They abound in the Mediterranean, and are scattered over the German Ocean. The more remarkable species live at considerable depths, and come rarely under the notice of the zoologist; but some are littoral, lurking among sea-weed and in the crevices of rocks, while others burrow in the sand. They appear to be gregarious, and are evidently by their organization very limited in their powers of locomotion. When they reluctantly remove from their sites, it is by the aid of their tentacular suckers; thrusting these forward to the utmost, they fix them to the ground, and drag the body on at a pace slower than the shadow on the dial. By the same organs they retain themselves in their natural positions, and effect a safe anchorage when the sea is agitated to the bottom. Otho Fabricius says of Holothuria pentactes, that it can swim,[3] a sort of exercise which the structure of the creature would not lead us to predicate; but the fact appears to be confirmed by Bosc, who tells us that the Holothuriæ swim slowly, as much by a kind of vermicular motion as by that of their tentacula, and the faculty which they possess of inflating the body at will.[4]

We learn from Delle Chiaje, that some of the Holothuriæ are eaten by the poor inhabitants of the rich shores of Naples; and the Sipunculus edulis (Lumbricus edulis, *Pallas*) serves as food for the Chinese who inhabit Java, and who search for it in the sand, with little bamboo sticks prepared for the purpose.[5] Their appearance is to us loathly, and they breathe no Sabæan odour; yet the celebrity of the *Trepang*, a species of Holothuria,[6] must rescue the family from contempt in the eye of every liberal epicure, who, rising above national prejudices, allows his Chinese brothers to extol unchecked their treasures of the stormy seas. "This animal," says Professor Jameson, "is used very extensively by the Chinese for culinary purposes. They make of it a very rich and palatable soup, and dress it in different kinds of stews. There are various modes of curing it. It is first gutted and the water pressed out of it, and then laid in dry lime, called by the natives *chunam*; afterwards, according to the circumstances of the fishing station, dried in the sun, or on stages by means of fires of wood under them. It is a most important article of commerce, and is the most considerable article of the exports of the Indian islands to China, unless perhaps pepper. There are fisheries, as they are called, of trepang, in every country of the Indian Archipelago, from Sumatra to New Guinea. It has also within these last few years been discovered abundantly on the coasts of Ceylon and the Isle of France, and is no doubt general throughout those seas. It has, as we are informed, already been sent from thence to China, where it finds a ready market, although, from its being unskilfully prepared, it is classed with the lowest qualities of the archipelago. When the Chinese can be employed in fishing and preparing it, there is little doubt that it will form an important article in the commerce of those countries with China, as it can be got in any quantities." After some farther details relative to the mode of fishing and curing it, the professor adds, "the whole quantity sent to China from Macassar, and other parts of India, may be estimated at 14,000 piculs. Taking this quantity at the low average of forty dollars a picul, and valuing the dollar at 4s. 3d., its entire value, in a commercial view, is L.119,000. Notwithstanding this enormous export to China, we do not understand that its value in the market has ever been materially affected by the quantity imported; an evident proof that the demand of the market still exceeds the supply. When we reflect that the opium, pepper, birds' nests, sharks' fins, trepang, and various other articles, the products of the countries under our control, which are fully as indispensable to the Chinese as the teas of China are to Europe, the fear so much entertained of the Chinese interdicting our trade with that empire is quite preposterous. In short, these few articles of luxury give us the command of the Chinese tea market. The celestial empire cannot exist without its trepang and birds' nests."[7]

The systematic arrangement of the order has kept increasing in complexity with the discovery of new species, and their minuter examination. Linnæus found two genera sufficient in his time, viz. "Sipunculus—corpus teres, rostro cylindrico angustato;" and "Holothuria—corpus ore antico, tentaculis carnosis antice cinctum."[8] Pallas referred the latter to Actinia, of which they formed a section, distinguished by having two apertures to the alimentary canal; for it was the opinion of this great naturalist, that differences of structure, which, in higher grades of animals, were justly reckoned to be of generic value, were in worms to be deemed not more than specific.[9] The family, nearly as we view it, was first defined by Lamarck, who made it embrace five genera, that stood in three separate sections, thus:

* 1. Actinia :
* * 2. Holothuria ; 3. Fistularia :
* * * 4. Priapulus ; 5. Sipunculus.[10]

In the *Règne Animal*, the Echinodermata form two orders, the pedaneous and the apodous. The Holothuries are one of the families of the first, while the species which Lamarck would have referred to his third section constitute the entire second order. Cuvier throws the Holothuries into unnamed groups, from peculiarities in the distribution of the tentacular suckers; and his apodous genera are Molpadia, Minyas, Priapulus, Lithodermes, Siponculus, Bonellia, and Thalassema.[11] The latter is now generally allowed to belong of right to the class Vermes.

Latreille's arrangement is little other than the reduction of Cuvier's to named divisions, as will appear from the following outline of it.

Class—HOLOTHURIDA.

Order I.—Apoda.

Fam. 1. *Lombriciformia.* Mouth unarmed. Genera—Bonellia, Siponculus, Miniada.
2. *Veretriformia.* Mouth armed with osseous pieces.—Priapulus, Molpadia.

[4] *Hist. Nat. des Vers*, ii. p. 148.

[5] Griffith's Cuvier, *Moll. and Rad.* p. 455, pl. 12, fig. 3.

[6] The species does not seem to have been ascertained. Mr Collier and Professor Jameson refer it to *Holothuria tubulosa*: Professor Grant says that it is the *H. ananas* (*Outl. of Comp. Anat.* p. 332); while Lesson calls it *H. edulis*, which is the type of a new genus named *Trepang*. From Collier's figure, it appears to be apodous, and also destitute of tentacula, so as much to resemble an Ascidia (See *Edin. New Phil. Journ.* viii. p. 47, pl. 1, fig. 1); but his description corrects these iconographical defects.

Echinodermata.

Order II.—**Polypoda.**

Fam. 1. *Vagipedes.* Feet scattered over the whole body. Genera —Holothuria, Actinopoda, Fistularia.

2. *Inferipedes.* Feet ventral only.—Phantapus, Phalloide.[1]

Blainville's method of classifying the proper or pedaneous Holothuridæ is exhibited in this neat synoptical table :

Body	flattened, with suckers underneath	*Cuvieria.*
	subprismatic, with inferior suckers	*Holothuria.*
	fusiform, with scattered suckers	*Thyone.*
	vermiform, with pinnate tentacula	*Fistularia.*
	subpentagonal, with suckers in ambulacra	*Cucumaria.*[2]

But the host of species discovered within these few years, during the voyages undertaken for the promotion of the natural sciences, has proved the inadequacy of these systems; and although the researches of Jœger and Brandt, with ample materials at their disposal, have brought into operation characters of a higher value on which to found a better arrangement, that good work has not yet been satisfactorily accomplished. The characters on which the naturalists mentioned have proposed to proceed, are derived from the absence or presence of the tentacular suckers, their homologous structure or dissimilarity, the existence or not of the aquiferous branchial apparatus, the pattern after which the suckers are disposed, the floating character or adhesion of the respiratory organ, and, lastly, the variations in the tentacula which guard the mouth. Guided by these characters, whose importance is in the order stated, Brandt has worked out a genealogy of the family, perplexing from its numerous subdivisions; but it is confessedly the basis of that lately offered to us by Blainville, and which we now analyse; for, however dry and barren such tables may seem to be, it is really from their careful study that the student obtains his clearest view of the forms and general structure of the species. "The use of synoptical tables in every branch of science," says Mr Duncan, "is obvious. They afford great aid to memory; but also, on frequent review, they suggest continually to the inquiring mind new traces of undiscovered relations."[3] Blainville's new method of distributing the species, then, is as follows :[4]

A. H : VERMIFORMES.

Body elongate, soft, vermiform ; the *feet* small or none.

No suckers ; tentacula pinnate	1. Synapta, *Eschscholtz.*
No suckers ; tentacula pinnatifid	2. Chirodota, *Eschscholtz.*
Suckers small, in five bands	3. Oncinolabes, *Brandt.*

These species are closely connected with the apodous Entomozoa by the Siponculus, the Priapulus, and perhaps even the Molpadia. The first species, instead of feet or suckers, have the body covered with small crotchets, by which they anchor themselves to submarine rocks, &c. Their tentacula are continually in motion, moving towards the mouth. There is no cloacum, the anus being strictly terminal; and there is no aquiferous respiratory dendroidal apparatus.

B. H : ASCIDIFORMES.

Body short, coriaceous, convex above, flattened below, with the *orifices* superior rather than terminal.

The skin scaly	4. Cuvieria, *Peron.*
The skin rugose but soft	5. Psolus, *Oken.*

C. H : VERETILLIFORMES.

Body considerably elongated, softish, subcylindrical, covered throughout with *tentacular suckers*, of which the inferior are the longest.

The anus widely patulous	6. Holothuria.
The anus plaited	7. Bohadschia, *Jæger.*
The anus closed, with five teeth or scales	8. Mulleria, *Jæger.*

D. H :

Body more or less elongated ; the inferior *suctorial feet* longer than the superior, and disposed in a determinate number of longitudinal rows.

The suckers in three rows	9. Stichopus, *Brandt.*
The suckers in five rows	10. Diploperideris, *Brandt.*

E. H : CUCUMIFORMES.

Body but little elongated, more or less fusiform, pentagonal, with the *tentacular feet* forming five ambulacra, one along each angle.

The feet small or obsolete	11. Liosoma, *Brandt.*
The feet very obvious, and tentacula pinnate	12. Cladodactylus, *Brandt.*
and tentacula pinnatifid	13. Dactylota, *Brandt.*

The species in this section connect the family with the Echinides.

F. H : SIPONCULIFORMES.

Body more or less suddenly narrowed behind, the pentagonal figure indistinct, without *ambulacra*, and perhaps without *tentacular feet* : tentacula simple, short, and cylindrical, as in Actinia.

Embraces only the genus....................14. Molpadia, *Cuvier.*

Still more recently the order has been reviewed by Agassiz, and because of the influence which his views will probably have with naturalists, we deem it necessary to give the names of his genera, to which we shall add their synonymes, and the number of species he enumerates as belonging to each. Agassiz rejects from the order all echinoderms which are not strictly referable to the Linnæan genus Holothuria, a genus of family rank, and divisible into,[5]

	Species.
1. Synapta, *Esch.* = Fistularia, *Bl.* = Tiedemannia, *Leuck.*	8
2. Chirodota, *Esch.*	4
3. Thyone, *Oken.* = Mulleria, *Fleming*	7
4. Trepang, *Jæg.*	2
5. Holothuria, *Lin.* = Fistularia, *Lam.*	23
6. Mulleria, *Jæg.*	2
7. Bohadschia, *Jæg.*	5
8. Cuvieria, *Peron.*	2
9. Psolus, *Oken.*	3
10. Pentacta, *Goldf.* = Cucumaria, *Cuv.*	9
11. Minyas, *Cuv.*	1
	66[6]

ORDER II.—ECHINIDES,[7] LAMARCK.

The Echinides are popularly known by the name of sea-urchins or sea-hedgehogs, given to them from their shells being covered with moveable prickles like the skin of those quadrupeds ; "Horret capillis ut marinus asperis Echinus ;" but when the prickles have fallen off, the shells are more commonly called sea-eggs, partly from a conformity in the figure between the objects compared, and more so from a similarity in their calcareous composition and texture. From their forms, certain genera have been also called turbans, diadems, mermaids' skulls or hearts, or fairy-stones ; a nomenclature more pleasing to us than the Greek compounds of science, and not more poetical than useful, since it aptly conveys a portraiture of those varieties in which nature has, with her usual sportiveness, moulded these productions. It is from this variety that a general description of the shell becomes impossible ; and to form a correct idea of its beautiful and complicated mechanism, it is necessary to select one as a type or standard for comparison and further description. For this purpose we shall take the shell of the common Echinus (*E. esculentus*).

The shell is of a globular figure, with a flattened base, formed of ten conformable plates, alternately broad and narrow, and ten annectant ones dissimilar in character. All of them proceed from the rim of the oral aperture in the base, and rise upwards, bellying in the middle, whence they again converge, and are united in a circle opposite the mouth by a series of small pieces to be afterwards described. The first series of plates is called *areæ* by Linnæus ; and those by which they are joined together, and which are all narrow and of the same size, he named the

[6] For the specific characters of all the species hitherto described, we refer the student to the 2d edit. of Lamarck's *Anim. sans Vert.* tom. iii. ; and the British species will be figured and described in Mr Forbes's work on our native Echinodermata.

[7] Synonymes : Echinida ; Echinina ; Echinidans.

Echinodermata.

ambulacra, from a resemblance his rich fancy traced in them to the walks between the parterres of a garden laid out after the olden fashion. The *areæ* are thickly studded with tubercles of different sizes; and when more narrowly examined, it will be seen that each *area* is divided down the middle, by a zigzag line, into two equal halves, composed of numerous small pentagons set in cross rows, and dove-tailed into each other with the most perfect adaptation, the projecting angle of one series being fitted into the concave angles of the other. Their tubercles support the spines, which move on a pearly globular pivot that sinks into a corresponding cup in the base of the spine, and where they are retained by the soft epidermis or skin that covers the entire shell in its fresh condition. The spines are calcareous, columnar, very often large in proportion to the shell; but with these primary spines smaller ones of three kinds are numerously intermixed, viz. one of the same form, differing only in size; another slender as a hair, but dilated into a club at each end; and another on a flexible stalk supporting three moveable prongs placed in a triangle, not very unlike the trident of Neptune. These Müller mistook for parasitical polypes; and we still find them in many systems forming the genus *Pedicellaria* among these animals. Their function is unknown; for Monro's conjecture that they supply the place of the organs of the senses in the more perfect animals, is a very loose one, and improbable.[1] The *ambulacra* are joined to the areæ by a plain or even suture, and instead of being tubercled, they are perforated from top to bottom with holes, always disposed after a regular pattern, which probably varies in every species. These holes give exit to numerous fleshy tubular pedicles, whose apex forms a circular testaceous shield, serrulated round the rim, concave and perforated in the centre, and formed of six distinct pieces, united by a plain elevated suture. If we now examine the top of the shell, we find it occupied by a small circular tuberculated plate, with a hole in its centre (the *vent*), and the plate surrounded by five triangular scales, and five less ones of a lunate figure placed exterior to and between them. The triangular scales, called the *ovarial* by Mr Gray, are each of them perforated with a hole leading to the ovaries, and they stand opposite the large *areæ*, into an emargination of which the point of the triangle dips, while the lunate scales, the *interovarial pieces* of Mr Gray, embrace the points of the small *areæ* and the *ambulacra*, and are likewise perforated with a hole scarcely visible to the unaided eye, and the use of which is quite unknown. "One of the *ovarial* plates is considerably larger than the rest, convex externally, and perforated like a sieve with numerous minute foramina, and internally thick and rugose. This plate is somewhat similar, both in form and perhaps in use, to the orbicular spot on the back of the Stellerida, called *corpus spongiosum* by Spix."[2]

This description of the crust or shell of the Echinides, it will be remembered, is in a great degree specifical, and will not apply universally even to the globose species, from which it is especially drawn; and it must less accurately apply to those which are greatly depressed, or oval, or heart-shaped, or cranial, or which rise up in the form of a conical pentagon. In all these the *ambulacra* are often only half of the typical number, and often only partial in their extent; while the *areæ* become coalescent, amalgamating more or less completely, with a consequent loss in the distinctness of their radiation. In many of these, also, the oral aperture loses its central position, and gradually, through a succession of genera, approaches the margin, which in some it occupies; the vent being subjected in its position to the like variations, and drawing with these, alterations of equal extent in the other exterior apertures. Nor in shape and armature does the mouth vary less. It is circular in the true Echinus, and armed within with a most complex apparatus of calcareous jaws, arches, and teeth, consisting of twenty-five separate pieces; while other genera, nearly allied, present the strange contrast of having no trace of these parts, being wholly toothless, with the outer aperture transformed into a narrow transverse labiated slit. To fill up the interval between these extremes, there are genera which have an oral apparatus less complicated than that of the Echinus; for in natural orders or families there are no abrupt transitions in structural organization. Amid all their varieties there reigns an evident connection and harmony, indicating a design or plan after which they have been called into existence; and in contemplating that unity of purpose, and the beauty and intricacy of the workmanship bestowed on the individuals created to fulfil that purpose, we endow them with our superior intelligence, and give utterance to their evidence of the existence and attributes of the Deity.

Echinodermata.

From the differences just indicated in the structure of the mouth, we naturally and correctly infer that there will be a corresponding diversity of the food on which the Echinides subsist. The jawless Spatangi burrow in the sand, and, swallowing the earth around them, extract a hard nutriment from the decayed animal and vegetable matter intermixed; but the Echini live amid rocks near low water, trace their crevices, and there seek the small crustaceous and testaceous Mollusca, whose shells they are enabled to break by the power and hardness of their teeth. Cavolini indeed asserts that the Echini live upon sea-weed; but the testimony of Dr Monro to the contrary is equally positive, and more consistent with the anatomical structure. That great anatomist tells us that they prey upon living Buccini, "as I had found particles of shells in their alimentary canal;" and they seize and secure their prey by means of the suctorial tubes which garnish the ambulacra. "I therefore directed the fishermen to bring me, along with the Echini, some living Buccina; to which, as I had supposed they would do, they attached themselves so effectually, that when I lifted the Echinus out of the water, I found it could support with ease a Buccinum which weighed nearly a quarter of a pound."[3] "The Echinidans," says Mr Kirby, "whose station appears to be often near the shore, upon submerged ledges of rocks, feed upon whatever animal they can seize. We have seen that they sometimes turn upon their back and sides, as well as move horizontally. This enables them more readily to secure their food, with the aid of the numerous suckers in the vicinity of their mouth, which, when once they are fixed, never let go their hold till the animal is brought within the action of their powerful jaws. Lamarck thinks they do not masticate, but only lacerate their food; but as two faces of each of their pyramidal organs answer those of the two adjoining ones, and these faces are finely and transversely furrowed, this looks like masticating surfaces. Bosc, who appears to have seen them take their food, says it consists principally of young shell-fish and small crustaceous animals. As the latter are very alert in their motions, it is difficult for the sea-urchins to lay hold of them; but when once one of these animals suffers itself to be touched by one or two of the tentacles of its enemy, it is

---

[1] It has been recently stated, that the animal uses them as grapnels to attach itself to sea-weeds. Our native species covers itself, when residing between tide-marks, with fragments of sea-weeds, evidently as a means of concealment; and we believe they are held on the shell by means of these organs, which are a sort of self-acting forceps.

Echinodermata.

soon seized by a great number of others, and immediately carried towards the mouth, the apparatus of which developing itself, soon reduces it to a pulp."[1]

The intestinal canal which this food has to traverse is, like that of the Fistulides, long, cylindrical, and tortuous, with a vent separate from the mouth. There is no chylopoetic viscus; but Blainville deems to be hepatic some glandular spots which he has detected in the parietes of that portion which may be regarded as stomach.[2] The intestine is fringed throughout with a mesentery, on the under edge of which Monro found two vessels without valves, nearly equal in size and parallel to each other, which he injected with quicksilver, and from them filled a beautiful net-work of vessels, not only on the intestines, but dispersed on fine membranes, which tie the intestine to the inner side of the shell. "I could not however," he continues, "observe that these two vessels communicated with each other directly, nor by the medium of any organ like to our heart; nor could I observe in the living animal any beating organ like to the heart; yet near to the anus, and connected to the rectum, which is the place of the heart in many other worms, I found a small organ, which seems to be hollow. It appears to be highly probable that one of these vessels is the principal artery or aorta, and the other analogous to our vena cava; and that they communicate by invisible branches, and circulate the blood by the muscular action of their coats, without the intervention of a heart, nearly in the way the vessels in fishes carry the blood from the gills back to their heart."[3] Blainville however, with a full knowledge of Monro's opinions, and of subsequent discoveries, aided too by his own dissections, acknowledges that he cannot tell which vessels are arterial and which venous, and thinks it very possible that there is no such distinction in animals so low in organization as the Echinides, the vessels being at one and the same time both arteries and veins.[4] How the blood circulates is therefore a subject of conjecture; but we know more precisely the manner in which it is aerated. Lying along the inner surface of each of the *ambulacra*, there is a branchial leaf or doubled membrane, "not unlike the processes or subdivisions of the gills of a skate," and having a direct communication with the external tubular suckers, already described as pullulating from the ambulacral pores. The water sucked in by these tubes gains access within the shell by two of the pores (for there is a pair to each sucker), and by their divergence is carried into the opposite folds of the branchiæ. Here one portion of the sea-water is supposed to be exuded into the general cavity of the shell, between its inner covering and the intestine; while another portion is again collected, by anastomosing vessels, into five large ducts, that terminate, each by two branches, in large sacs or receptacles over the sockets of the teeth, communicating with each other; and from these the liquor passes down the sockets of the teeth, and is discharged into the sea, on each side of the tooth, between the socket of the tooth and beginning of the œsophagus.[5] Such is the course of the fluid as described by Monro; but later anatomists maintain that the current has in fact exactly the reverse direction; and they inform us that the sea-water which fills the interior cavity is introduced through certain membranous tubes, arranged in ten small groups round the oral aperture in the base of the shell. Be the fact as it may, there remains a provision of aqueducts most curiously contrived for conducting the medium of respiration and assimilation through the body; and very probably the current is propelled and directed in its way by the action of vibratile cilia, which, in these animals, as in most others, clothe all the serous surfaces of the internal viscera, keeping the fluid in contact with them in perpetual change and renewal, and not allowing it to stagnate even on the outer shell.[6]

The ovary or roe occupies much space within the shell, being very large in proportion to the animal and its other viscera. It is divided into five or four lobes, disposed radiantly, each lobe having a distinct exterior aperture, as well as a communication with each other. The apertures are placed round the anal when this is central, but otherwise their relationship is not so regular and constant. It is probable the ova, after their extrusion, undergo no change analogous to a metamorphosis.[7] We have examined the young of Echinus esculentus when it did not exceed one-eighth of an inch in diameter, and then it had the form and armature of adultness; but the prickles were toothed along their sides, and the forcipated organs appeared to have only two prongs. The pieces of which the shell was built were few in number, and the spines round its base were most developed, but the globular form was as perfect as when full grown. It is enlarged in its growth, partly by the deposition of new matter on the edges of the pentagons of which the areæ are constructed, and partly by the formation of additional pieces intercalated among the others. These new pentagons are formed principally near the dorsal summit, where the connection between the areæ and ambulacra remains loosest. "If, carrying the examination still farther, we remove the spines, we shall then observe that amongst the oviducal and interoviducal plates, and the interambulacral plates that bear spines, there are some less fully developed, irregular in form, wanting even the mammellæ and the spines, and taking their place among the mammellated plates only in proportion as they gradually attain to a larger size. The new plates are at first very small, and may be compared to points of ossification, which at first grow simultaneously in all directions, though their lower side completes its formation sooner than the upper, and the upper side is sometimes yet incomplete, even when an incipient mammella is observable in the middle of it. In the region of the body where this increase takes place, the membrane which unites all the plates, and spreads itself over their surface, forming an articular capsule about the base of the spines, is softer and more spongy than it is in the inferior part, where the plates are consolidated and immoveable. It is in fact this spongy mass that deposits the calcareous matter of which the plates are composed; and the spines shoot out in the centre almost in the same manner as the horns of a stag. They do not become moveable until they have attained a certain stage of development; and there is a period in their growth after which their size does not increase. Those however which drop off accidentally are replaced by others, formed, as those had been, by the tumefaction of the membrane which covers the plates. We may always observe, in a single specimen of the *Cidaris*, all the gradations of increase, from that of the plates which have completed their growth, and bear spines several inches long, down to the smallest points of ossification of the plates yet unfurnished with spines. These facts I have ascertained by examining several individual specimens, which exhibited all the intermediate stages of development through which the pieces in question must pass; and indeed, when we have no direct means of observing the growth of an animal in one individual, the only resource left us is to compare a great number of individuals, representing a

Echinodermata.

complete series of all the stages through which the species to which they belong has to pass before their growth is completed. The only difference between this process and the direct observation of any development is, that in the one case we observe in one and the same individual that succession of changes which, in the other, we trace through a series, as complete as possible, of several individuals. Such is the course that I have taken with respect to the Echinodermata. The young Echini have a small number of plates in each of their vertical series; they appear to be slowly increased in size by the deposition of calcareous matter at their circumference, until those which surround the mouth have completed their growth, and are entirely consolidated. The superior plates continuing to grow, increase, from the top downwards, the periphery of the body, which remains depressed so long as the inferior are the only plates consolidated; but in proportion as a greater number of plates becomes immoveable, and as there is formed, in the upper region, a greater number of plates reaching down to the circumference of the spheroid, the testa becomes rounded, and finally assumes a spherical form. It is to this cause that we are to ascribe the differences of contour exhibited by the Echini at different ages. In some species there are found individuals presenting even a pyramidal shape, and this takes place when there is still formed a great number of plates subsequently to the consolidation of those occupying the greater diameter of the animal's body. These facts sufficiently explain the gradual growth of beings which approximate more or less nearly to the spherical form; and shew how carefully we should guard against the introduction of nominal species in consequence of a mere difference of form resulting from age only.

"It would be interesting to trace the development of these animals *ab ovo*. But no naturalist has yet observed the state of the Echini on their first issuing from the egg. As to the spines, it is evident, especially in the *Cidarites*, that those surrounding the mouth are the first that attain their full growth, while the largest are those in the upper tier of the disc; and those which have not yet completed their growth are found around the oviducal plates on the outside. The correctness of these observations will be demonstrated by comparing the differences of development exhibited in this region by the spines that stand nearest to each other. We should be mistaken however as to the growth of the Echinodermata, did we think that there is a generic connection between the plates, on account of their forming vertical series from the mouth to the summit of the disc. It has been already remarked, that the plates of each space are alternately a little more elevated than each other; but no attention has been paid to the manner in which the plates of all the spaces succeed each other in the same Echinus; and yet, if we consider it closely, we shall see that the new plates are developed in spiral lines, passing without interruption from one series to another, through all the spaces from the circumference of the mouth to the dorsal summit, so that those which rest on each other in a vertical line do not make their appearance in immediate succession. It appears to me well worthy of remark, that in these animals, holding so low a rank among organized beings, we should find the succession of the solid parts composing the integument so strikingly analogous to the arrangement of the leaves around the stems of plants; an arrangement the laws of which have been recently discovered by M. Schimper, and explained, so far as regards the *Coniferæ*, in a memoir of M. Braun on the arrangement of the scales of their cones.

"The small plates surrounding the mouth, and those around the anus, are arranged in a peculiar manner. They are easily moved, and thus facilitate the deglutition of the food, and the voiding of the excrements. In general the testa of the Echini is not so immoveable as one who had not observed them in a fresh state might be led to suppose. All the plates forming the upper part of the disc are often set in motion; sometimes they sink, sometimes they rise, and, in the oblong species, the longitudinal diameter is often extended beyond its ordinary length."[1]

The Echinides are in general littoral animals. The species with a thin brittle shell, covered with small hairs like bristles, as the Spatangi, burrow in the sand, covering themselves up by the aid of their spines; but those with a stronger prickly crust hide themselves in rocky places. Looking at their rotund limbless forms, we might imagine that they must constantly be fixed to one spot, or, if moveable, that, from the difficulty in bringing members so numerous and opposite to co-operate, or from hesitation in what tract to move, seeing that they are all alike and look to all sides, still a perpetual sedentariness would be their choice. But it is not so, and their motions are neither less regulated nor slower than those of the majority of avertebrated animals. They usually advance on their flat basis, but when an individual chooses, it can move forward by turning on itself like the wheel of a coach. From the nature of their localities, they are much exposed to bruises, and worse foes in the shape of fish and worm. The latter they repel by their spinous panoply, which they can erect and stiffen, presenting a thousand spears on every side, and no point unguarded;[2] the bruises they bear with impunity, and it must be a wound only short of total disorganization from which they cannot recover. Monro has even seen the pieces of a broken shell walk off in different directions. By what organs the Echinides exercise their locomotive powers has been disputed. Most authors assign this duty to the spines of the areæ and the ambulacral suckers conjointly. Baster tells us, that the latter are the principal organs;[3] and, according to Blumenbach, they are the only ones,[4] the prickles being merely organs of offence and defence. Now, says M. Agassiz, this is a very erroneous opinion,—vox et præterea nihil,—for it owes its birth and continuance to a mere verbal influence, the term *ambulacra* being first translated into alleys or walks, and then the organs which grow in them were subsequently supposed to be the walkers. Without questioning this very questionable transition, we know that Agassiz is wrong in denying the tentacula their pedestrious function. "How, in fact," he asks, "could these small tentacula, with all their softness of texture, situated, as they generally are, in that part of the body which is never brought into contact with the ground when the animal moves, and overhung by calcareous solid spines; how, I ask, could those flexible tubes be used as organs of motion? It is an undeniable fact, and I have often observed it myself, that it is with their spines the Echini move themselves, seize their prey, and bring it to their mouths, by turning the rays of their lower edge in different directions."[5] Our own observations, on the contrary, have satisfied us that the common Echinus moves from place to place solely by the aid of the tentacular suckers; the spines, as Mr Couch correctly states, acting as levers or crutches. Agassiz exaggerates the littleness and weakness of the suckers: in the common Echinus, whose spines are not above half an inch in length, the suckers can be extended one inch and a half, so as greatly to overreach the spines; and they can at the same time be rendered firm and rigid

Echinodermata.

by distention, from water, and the contraction of their own muscular parietes. The spines are moved principally, we think. by means of the exterior irritable skin which covers the shell and envelopes their bases; but when these spines are very large, the tubercle to which they are articulated is perforated for the transmission of muscular fibres from within, and which appear to be inserted into their roots by a coronet of fibres.[1] The number of spines and suckers,—and let it be remembered that there are several muscles to every spine and every sucker,—on a single individual, is indeed wonderful. A specimen of Echinus esculentus, of moderate size, will have at least 160 primary prickles on each of the large, and 80 on each of the small areæ; that is, 1200 in all; but reckoning the lesser bristles, there will not be fewer than 3000: and there cannot be less than 100 suctorial tubes in each ambulacrum, making the number of exterior appendages in this creature 4000. We join in the conclusion of Baster: "Quod si jam musculorum, ad aculeorum et proboscidum motum necessariorum copiam animo concipiamus, Omnipotentem, quæ hæc animalia creavit, sapientiam attoniti et venerabundi adoremus, necesse est."[2]

The seas of warm and tropical countries are the most productive in Echinides; but the living species are few compared with the fossil, which are found principally in the chalk and oolite formations, in such abundance, and in so fine a state of preservation, that they are common and favourite objects in collections. Desmoulins has, in the following table, which, although incomplete, is interesting, exhibited the proportions which the extinct bear to the still existing species.

	Total No.	of which are living
Clypeastre	13	6
Scutella	35	21
Fibularia	17	9
Cassidula	5	0
Galerites	10	1
Pyrine	7	0
Echinometra	6	6
Diadema	14	7
Cidarites	28	12
Echinonée	2	2
Echinolampe	28	3
Nucleolite	22	1
Collyrite	11	0
Ananchyte	11	0
Spatangus	57	18[3]

The direct uses of the Echinides to man are few and trivial. As its name indicates, the Echinus *esculentus* is eaten in some parts of the south of Europe; Pennant says, "by the poor in many parts of England, and by the better sort abroad." They are in season in spring, when the ova are most developed, and nearly fill the shell. They are recorded as among the favourite dishes of the Greeks and Romans. "They were dressed with vinegar, honied wine or mead, parsley, and mint; and esteemed to agree with the stomach. They are the first dish in the famous supper of Lentullus, when he was made *Flamen Martialis*, priest of Mars. By some of the concomitant dishes, they seemed designed as a whet for the second course, to the holy personages, priests, and vestals invited on the occasion." Epicharmus describes them as used likewise at the marriage feast of Hebe: "Thither came crabs and urchins, unable to swim in the sea, but travelling only on the ground." In the Wasps of Aristophanes, the old dicast, who is the hero of the piece, repeats a fable respecting an urchin, who, when his shell had been cracked by a woman, summoned witnesses to prove the assault. He is interrupted by the remark, that it would have been much wiser for the creature to buy a bandage. Ennius, in his Phagetica, mentions "dulces echini," and "calvaria pinguia," the latter evidently a species of Spatangus, which, we also know from Aristophanes, was considered a very dainty morsel. The Echinus is several times mentioned in Horace as good eating. The shells, cleaned and bleached, are pretty ornaments, with which finical idlers dress up their moss or summer houses, and naturalists their museums. Some fossil species are called fairy-stones, their spines elves' spurs; and with these names were once associated, as we learn from Sir Thomas Browne, suitable and terrible apprehensions, as well as medicinal virtues; "common opinion commendeth them for the stone, but are most practically used against films in horses' eyes."[4] Once only has an Echinus been truly beneficial to our race. Some species of the genus Cidaris, we may observe, have very large prickles. The heathen children of the island of Rarotonga, in the South Seas, converted to Christianity by English missionaries, were in want of pencils with which they might be taught to write on slates; for these "they went into the sea, and procured a number of the Echinus, or sea-egg, which is armed with twenty or thirty spines. These they burnt slightly to render them soft, that they might not scratch; and with these flakes of stone for a slate, and the spine of the sea-egg for a pencil, they wrote exceedingly well; and hundreds of them took down the principal portions of every discourse they heard."[5]

We now proceed to give an analysis of a few of the modern methods of classification proposed for the Echinides. Linnæus, keeping his eye fixed on the recent species only, of which he knew no more than seventeen, reduced them all under one genus, believing, probably, that all previous attempts were premature; for he could scarcely regard the differences on which certain groups were previously grounded, as unimportant, or uninfluential over the habits of the animals. Müller did no more than give a name to the Linnæan sections, which were two, founded on the central or eccentric position of the anus;[6] and the Linnæan simplicity was praised and followed until the views of Cuvier, and the system of Lamarck, freed us from the thraldom of the great Swede, and generated a new spirit, too little regardless, perhaps, of authority, and too prompt to invent and promulgate novel plans, which have had however one good result, in bringing before us prominently and distinctly, structural peculiarities which were previously hid or disregarded amid the vagueness of the Linnæan generalities. The system of Lamarck is exhibited in the following table:

1. THE VENT BELOW THE MARGIN, IN THE LOWER SURFACE, OR IN THE MARGIN.

* *The mouth beneath, always central.*

Scutella, Clypeaster, Fibularia, } Ambulacra contracted.
Echinonius, Galerites, } Ambulacra complete.

** *The mouth beneath, not central, but approaching to the margin.*

Ananchites. Spatangus.

2. THE VENT ABOVE THE MARGIN, AND CONSEQUENTLY DORSAL.

* *The vent dorsal, but approaching to the margin.*

Cassidulus. Nucleolites.

** *The vent dorsal and vertical; the shell regular.*

Echinus. Cidarites.[7]

---

[1] See Kirby's *Bridgew. Treatise*, p. 207. The largest spine of an Echinus on record is that noticed by Mr Gray, "nearly an inch and half in circumference, and more than eight inches long." *Ann. of Nat. Hist.* i. p. 414.

[2] *Opusc. Subs.* i. iii. p. 113. Professor Grant says, "there are more than 10,000 pieces in the shell of the Echinus esculentus, without counting the complicated dental apparatus of the mouth, or the respiratory and ovarial plates, or the very minute calcareous pieces disposed irregularly on the coriaceous membrane around the oral and the anal orifices."—*Outl. of Comp. Anat.* p. 20.

[5] Williams's *Missionary Enterprises*, p. 409.

[6] Echinus.—"* Regulares: ano verticali. ** Irregulares: apertura ani subtus uti os." *Syst. Nat.* p. 1102 and 1104.

[7] *Hist. Nat. des Anim. sans Vert.* iii. p. 6. We have used Mr Parkinson's translation. *Org. Remains*, p. 119.

Echinodermata.

Of Mr J. E. Gray's arrangement, published in 1825, we can only give a bare outline, remarking that it is the only attempt which has been made to classify the Echinides after the views of Macleay. We have then, first, the

Typical Group.—*Body globular; mouth central, below; jaws conical, projectile, with five acute teeth; anus vertical, dorsal; ambulacra complete, forming bands extending from the mouth to the anus.*

Family I. Cidaridæ; of which the genera are, 1. Cidaris; 2. Diadema; 3. Astropyga.

Family II. Echinidæ: the genera, 4. Echinus; 5. Echinometra.

Annectant Group.—*Body not globular, variously shaped; jaws not projecting; anus lateral or below; anus and mouth covered with imbricate irregular scales.*

Family III. Scutellidæ: the genera, 1. Echinanthus; 2. Lagana; 3. Echinarachnius; 4. Echinodiscus; 5. Echinocyamus; 6. Cassidulus.

Family IV. Galeritidæ; with the genera, 7. Galerites; 8. Discoidea; 9. Echinanaus; 10. Echinocorys; 11. Echinolampas; 12. Echinobrissus.

Family V. Spatangidæ; embracing, 13. Spatangus; 14. Echinocardium; 15. Brissus; 16. Ova.[1]

Blainville's views of this order are shewn in the following synopsis of his method.

Mouth	Subterminal		Spatangus. Ananchites.
	Subcentral	Toothless	Nucleolites. Echinoclypeus. Echinolampas. Cassidula. Fibularia. Echinoneus.
		Armed with teeth	Echinocyamus. Laganus. Clypeaster. Echinodiscus. Scutella.
	Central; anus	infra lateral	Galerites.
		central	Echinometra. Echinus. Cidaris.[2]

From the researches of M. Desmoulins, it appears that Blainville would now unite Echinoclypeus with Nucleolites, Laganus with Clypeaster, Echinodiscus with Scutella; and Echinocyamus is probably not distinct from Fibularia, for although they stand in the table in different sections or families, Desmoulins finds that Fibularia ought to be transferred to that which is distinguished by its possession of teeth; and this also is the case with Cassidula.[3]

The arrangement of Agassiz may be thus epitomized.

ORDER ECHINIDES.

FAMILY I.—SPATANGIDÆ.

Body more or less elongated, gibbous; mouth with jaws, subanterior; anus posterior, sometimes on the upper surface of the disc, sometimes on the lower; shell thin, granulous, the spines setaceous, often compressed and unequal. The anterior ambulacrum is generally less developed than the rest. They form round the mouth grooves, where the holes are larger, and whence proceed ramified tentacula, like those of the Holothuriæ. There are only four oviducal plates, which are very distinct.

1. Disaster, *Ag.*=Spatangus, Ananchytes, et Nucleolites, *Auct.*
2. Holaster, *Ag.* = Spatangus, *Auct.*
3. Ananchytes, *Lam.* = Echinocorys, *Breyn.* Galea et Galeola, *Klein.*
4. Hemipneustes, *Ag.* = Spatangus, *Auct.*
5. Micraster, *Ag.* = Spatangus, *Auct.* Brissoides, *Klein.* Amygdala et Ovum, *V. Ph.*
6. Spatangus, *Klein.* = Echinospatangus, *Breyn.*
7. Amphidetus, *Ag.* = Echinocardium, *V. Ph.* Spatangus, *a. Bl.*
8. Brissus, *Klein.* = Echinobrissus, *Breyn.* Nuces, *V. Ph.* Spatangus, *d. Blainv.*
9. Scihzaster, *Ag.* = Echinocardium, *V. Ph.* Spatangus, *b. Bl.*

FAMILY II.—CLYPEASTRES.

Body generally circular; mouth central or sub-central; anus more or less approximated to the periphery, found sometimes at the upper, sometimes at the under surface of the disc.

1. Catopygus, *Ag.* = Nucleolites, *Auct.*
2. Pygaster, *Ag.* = Nucleolites et Clypeus, *Auct.*
3. Galerites, *Lam.* = Conulus, *Klein.* Echinochonus, *Blainv.*
4. Discoidea, *Klein.* = Conulus, *Leske.* Echinodiscites, *V. Ph.* Galerites, *Lam.*

FAMILY III.—CIDARITES.

Shell spheroidal, with two kinds of spines, the first larger on large mammillæ, the others smaller, surrounding the base of the first, or covering the ambulacra. Mouth central, inferior; anus opposite, on the summit, opening between the small laminæ surrounding it, opposite and sometimes very near to the posterior ambulacral space.

1. Cidaris, *Lam.*
2. Diadema, *Gray*, part of Cidarites, *Lam.*
3. Astropyga, *Gray*, —— Cidarites, *Lam.*
4. Salenta, *Gray*, —— Cidarites, *Auct.*
5. Echinometra, *Breyn.* —— Echinus, *Auct.*
6. Arbacia, *Gray*, —— Echinus, *Auct.*
7. Echinus, *Linn.*[4]

ORDER III.—STELLERIDES,[5] Lamarck.

The "seas have stars," sings Du Bartas; and if challenged, he would probably have appealed to the members of this family in proof that his fancy was in this instance not more licentious than his verses.[6] But it is only some species which have felt the skyey influence over their forms; for even certain of the Asterias are merely pentagonal, and some square, while the total forms of other genera rather imitate a wheel in their facies, with spokes radiating from a central navel: and others again have sought no impress from any object in the heavens or in earth; for though they have been called "lily-shaped animals," yet is the semblance but postulatory, and he must have a more assimilating fancy than our own who perceives it in these objects. Amid this diversity of forms, we may nevertheless remark, that a line drawn so as to connect the species of the rays together would give a circular outline to the body, which is very rarely protuberant, and never globular. It consists of two parts, the disc and the rays; the latter either continuous and homologous, or dissimilar and articulated to the other by the medium of peculiar scales. There is always a distinct dorsal and ventral surface; the former in general vividly coloured, and covered with spongeous tubercles or scales, whose office is defensive; the latter colourless, and furnished with the organs of locomotion and of touch. The colour resides in the mucous coat that occupies the place of the epidermis of higher animals, but the scales and tubercles are essentially parts of the thick cretocoriaceous skin which gives figure and consistency to the whole. In this skin there is deposited a considerable proportion of carbonate of lime, with some phosphate of the same earth, sometimes in the form of scales, either imbricated or scattered; more usually in grains or short pieces, so joined as to make a sort of knotted thread, that, by its divarications and anastomoses, is woven into a netted framework, the interstices of which are filled up by the mucous tissue. On the calcareous frame-work the spines and tubercles are placed, and these vary in size and structure according to their position. When dorsal, they are mostly short and obtuse, unordered and immoveable, excepting in so far as their degree of erection and relative position may be effected by the more or less turgid condition of the body; but on the sides of the rays, while their size is greater, they are also dressed in regular lines, and appear to be capable of being moved backwards or forwards by peculiar muscles. In the Asterias, the under surface of the rays is deeply furrowed from their origin to their extremity; and the furrow, analogous to the ambulacra of the Echinides, is occupied with two or four series of tentacular feet, which are also guarded by moveable spines, different in their structure, however, either from those of the back or sides, and forming a protective hedge on each side. There is nothing similar in the Ophiuridæ or Crinoidea, whose rays are not grooved, nor possess tentacular feet, but consist of a succession of similar pieces soldered to each other, so that they resemble the vertebral column of some slender animal, or, more exactly, from the squamous nature of the pieces, the tail of a lizard; and, like that tail, they are tapered and flexible to a certain extent, and equally brittle. It is interesting to remark, that this ray, apparently very dissimilar from that of the Asterias, really finds in that genus its type and original; for the roof, if we may so speak, of the ambulacral groove, is made up of a series of pieces catenated exactly like those of the Ophiuræ, with compressed processes arching up from each side after the manner of ribs, between whose intervals the tentacular feet are extended.

[5] Synonymes: Asterina; Asteroida; Stellerida; Stelleridea; Stelleridans; Les Astéries; Astéroïdes.

[6] Linckius begins his work "De Stellis Marinis" thus: "Non cœlo tantum, sed et mari suæ stellæ sunt, opera quidem unius Dei artificis, sed *diversæ prorsus fabricæ et naturæ.*" In his "Enquiries into Vulgar and Common Errors," Sir Thomas Browne has a chapter entitled "That all animals of the Land are in their kind in the Sea;" which, he rightly says, "although received as a principle, is a tenet very questionable, and will admit of restraint." After some good remarks, the chapter concludes with the following passage, and such passages abounding in the works of this learned physician, render them delectable reading. "Lastly, by this assertion we restrain the hand of God, and abridge the variety of the creation; making the creatures of one element but an acting over those of another, and conjoyning, as it were, the species of things which stood at distance in the intellect of God; and though united in the chaos, had several seeds of their creation. For although in that indistinguisht mass, all things seemed one; yet separated by the voice of God, according to their species, they came out in incommunicated varieties, and irrelative seminalities, as well as divided places; and so, although we say the world was made in six days, yet was there, as it were, a world in every one; that is, a distinct creation of distinguisht creatures; a distinction in time of creatures divided in nature, and a several approbation and survey in every one." Book iii. chap. 24

The mouth is situated in the centre of the ventral surface. It is a circular orifice, with a membranous lip, capable of great dilatation, but bounded by spinigerous and tuberculated angular projections, formed by the convergence of the bases of the rays, that may be useful in capturing and bruising the prey. A short œsophagus leads to the stomach, a large membranous sac occupying the centre or nave of the body; and though connected to the parietes by several ligaments, yet sufficiently loose and dilatable to permit of its frequent eversion and extrusion in the shape of bladdery lobes. It has no intestine, excepting in the Crinoid family, where there is a distinct vent opening on the inferior surface, near the mouth.[1] But the nutritive parts of the food pass from the stomach either into sacculated reservoirs, as in Ophiura, or through narrow vascular passages into large complicated cæcal appendages, which lie along the floor of the rays, two in each ray, consisting of a regular series of pectinations or overlying lobules, and having no unapt resemblance to some beautiful compound leaf or fern. Such organs we find in the Asterias; and as it circulates through them, the chyle is largely subjected to the influence of the oxygenating medium, and prepared for its assimilation. Such at least is the opinion of Tiedemann; but it may be necessary to mention, that Cuvier, Blainville, and Meckel regard these cæca as secreting organs, analogous to the biliary organs of many invertebrate animals, with which, says Dr Sharpey, it must be allowed they agree in several respects. In the living animal they are bathed, or rather float, in sea-water, which is presumed to be introduced within the body by means of numerous small tubular filaments that rise up on the back between the tubercles, penetrating the soft parts of the skin; and it is ascertained that the water, after a time, may be expelled through the same conduits,[2] for there is no doubt of the animal's ability both to fill and empty its body. The animal, observes Dr Sharpey, slowly distends itself with the water, "and again, but at no stated interval, gives out a portion of it: this is obvious from the fact, that the same animal may be seen distended at one time and flaccid at another. Naturalists are generally of opinion that the water enters and issues by the respiratory tubes (or dorsal filaments), and indeed no other orifices have been discovered; we must however freely own that we have never been able actually to observe its passage through these tubes." In the Ophiuridæ, in whom these tubes are not to be found, there must certainly be other entrances for the fluid; and these are probably certain orifices situated on the ventral surface, near the base of the rays. The water, however introduced, is there for the purpose of respiration, the principal seat of which seems to be the peritoneal membrane. "Spread over the viscera and the parietes of their containing cavity, and lining the respiratory tubes, it presents a great extent of surface, continually in contact with the surrounding medium; and we have found that a beautiful provision exists for maintaining currents of water along the membrane, and thus effecting that constant renovation of the fluid in contact with its surface which is required in the respiratory process. These currents are produced by means of cilia."..."Ciliary currents take place also on the external surface of the body, which probably partakes in the process of respiration; we have moreover observed them within the tubular feet, and on the internal surface of the stomach and cæca: in this last situation they are probably subservient to digestion."[3]

The mode of progression of the Stellerides is probably limited to a sort of creeping;[4] but their walk is not so slow as the language of most authors would induce us to believe; nor have we been able to ascertain, from many observations, that any one or two rays have a preference for the van, as has been insinuated, but whatever ray happens to point toward the object or place in view, is made the leader for the time being. The organs of locomotion are very dif-

[2] Reaumur in Linck. *de Stell. Mar.*, App. p. 93. Ehrenberg has discovered that these filaments are inwardly clothed with vibratile cilia, and he believes there is within them a circulation, not of water, but of a fluid analogous to blood; for he says we see in it globules altogether like the blood-globules of other animals. *Ann. des Sc. Nat.* n. s. iv. p. 304.

[3] Sharpey in *Cyclop. of Anat. and Phys.* ii. p. 40.

[4] Baster (*Opusc. Subs.* i. p. 119) and Bosc say that the Asterias can also swim. "In this act they suspend themselves obliquely in the water, and with their rays produce slight undulations, which suffice to direct their course. When they wish to descend, they cease these motions, and immediately sink to the bottom." *Hist. Nat. des Vers*, ii. p. 125. Blainville has seen certain species of Asterias swim swiftly. *Man. d'Actinologie*, p. 241.

Echinodermata.

ferent in the different families. The rays of the Asterias, as already mentioned, are broadly furrowed underneath, the furrows planted with soft tentacula, which are flexible in every direction, being moved by circular and longitudinal muscular fibres, which enter copiously into their structure. In form, these tentacula may be compared to a retort or florence-flask with a long neck: the swollen vesicular bulb is placed within the cavity of the rays on each side of their mesial vertebrated column, while the neck issues from between the interstices of its side-pieces, and protrudes outwardly. They are hollow, being filled to a certain degree with water, introduced by a set of ramified internal vessels, which constitute an aquiferous system, similar to that which we found in the Holothuriæ.[1] When the star-fish wishes to elongate any particular tentaculum, it contracts the vesicular bulb, and the water in it is consequently forced up the neck, distending and stretching it, and putting it in a fit condition to be applied against the ground or any object within reach. To this the extremity is affixed by the action of the muscular fibres, some contracting the centre of the point into a dimple, and others firmly appressing the edge, so as to give it the form as well as the virtues of a sucker. Now, by shortening the tubes which have been so fixed, the body is drawn towards their insertion; and by a curious succession of these actions, the creature goes whither it has willed.[2] It is impossible to follow the exact succession of the retraction and elongation of the suckers, nor indeed do they seem to be called into action after any regulated plan. Some are employed as stilts merely, on which the body is raised up buoyant in the circumfluent medium, while others are pulled in and stretched out to act as legs or feet; and others again seem to be used, more especially for the time, as seekers and feelers, that no prey may pass unawares, while the main object in view is apparently only a change of place. But the Ophiuræ progress by a very different apparatus. " The diverging rays are firm and hard, have few spines, and no channel with suckers; they are used by the animal as legs, and as they are regularly placed, it can move in any direction that suits it. To go towards any particular spot, it uses the two rays that are nearest to it, and another that is most distant from it; the two first curve at their extremity, so as to form two hooks, which, being applied to the sand, drag the body forwards, while the posterior is curved vertically, and performs the part of a repelling lever."[3] This action of the rays is assisted by some subsidiary organs, which have been hitherto unnoticed. On examining the rays of a living Ophiura, we have noticed that every one of their articulations is furnished with a pair of strong sharp moveable claws, similar to those of many insects and crustaceans; and from their position under the lateral spines on the ventral aspect, not more conveniently placed for taking hold of a plain surface than their form has an obvious adaptation to that act. They are unquestionably organs belonging to locomotion, which seems to us to be further aided by some filamentous tentacula that issue from pores in the ventral disc, whose function, though mainly respiratory, may be in a secondary degree locomotive, by serving as stayers to support the body, and elevate it above the unevenness and friction of the surface traversed.

The nature and number of the senses bestowed upon the Stellerides is a subject of doubtful inquiry; for the organs of these senses are either so far removed from ours that analogy offers no clue to their function, or the resemblance is so forced and superficial that it may possibly lead us to very erroneous conclusions. There is no reason to doubt that the species are richly endowed with the sense of touch; but it is doubtful whether any part or organ possesses that modification of the senses on whose discrimination the luxury of taste depends. It is equally doubtful to us, whether any have visual organs, for that blindness is the lot of most of them is granted. Ehrenberg, however, when examining living specimens of the Asterias violacea, discovered a point of a bright red colour, precisely defined, and situated beneath and towards the apices of each of the five rays. This point he believes to be ocular; and to give scope and direction to the organ, the star-fish curls back the tip of the ray when in the act of progression. Ehrenberg succeeded in tracing some nervous filaments to the apex of the rays, where he also found a small ganglion placed near the eye. In front of this ganglion, towards the mouth, there are some jointed nervous fibres; but similar articulations are not visible in the nerves situated near the mouth itself, whence this illustrious naturalist concludes, that the noblest part of the nervous system is found towards the apices of the rays.[4] But what office are we to assign to those anomalous organs, which, in the Echinides, Monro has compared to insect antennæ? They exist in the Stellerides, principally on the sides of the rays hid among the spines. " Each consists of a soft stem, bearing at its summit, or (when branched) at the point of each branch, a sort of forceps of calcareous matter, not unlike a crab's claw, except that the two blades are equal and similar. When the point of a fine needle is introduced between the blades, which are for the most part open in a fresh and vigorous specimen, they instantly close, and grasp it with considerable force. The particular use of these prehensile organs is not apparent; their stem, it may be remarked, is quite impervious."[5]

The Stellerides are oviparous, the ovary forming a grape-like cluster, placed near the origin and at the sides of the cæca, for there are two ovaries to each ray. The eggs lie numerously imbedded in a colourless jelly, covered with a thin pellicle, and are at first equally colourless; but during their progress to complete development, they pass through a great variety of colours, and when fully formed, assume invariably the distinguishing shade observed in the adult animal.[6] They escape from the body by certain apertures, observable at the side of the mouth in the angle of separation of the rays; and the greater number of the species are said to deposit their spawn in spring. When excluded from the egg, they are, according to Saars, very unlike the parent, for they are then binary, and do not become radiated until after some weeks.[7]

The Stellerides are richly endowed with the wonderful property of reproducing parts which they may have lost from accident. In summer, it is asserted by Bosc, the parts pullulate and attain their original size in the course of a few days, while in winter some months are required for such production; but this is one of those loose assertions in which the works of Bosc abound. The time really required is much longer, though not exactly ascertained, and seasons probably influence it in no great degree. One ray lopt off, or two or three, all grow again; nay, a single arm,

Echinodermata.

provided any portion of the disc remain attached, will live and become cinquefoil, as it was previously to its miserable mutilation. There was a time when these phenomena gave rise to expressions of the greatest wonder,[1] and to speculations more curious than edifying, touching the possible divisibility of the soul, and other metaphysical subtilties. We may safely from them infer, that the susceptibility to pain in these animals must be very considerably, and almost infinitely, less than in animals of a more perfect kind, since in these the pain consequent on such injuries, and the sympathetic fever which follows as its necessary result, would be sufficient to kill them, independently of any other cause.[2]

In relation to *habitat*, the Stellerides may be enumerated among the denizens of the shores of every sea, living generally at a depth of several fathoms, where they congregate in incalculable herds. There are beds of some species on our own coasts, that spread over an extent of some hundreds of yards, lying, in some spots, one upon another, to the thickness of a foot or more. The species are more various, if not more productive, in tropical than in temperate or cold seas. They prey upon small testaceous mollusca, which they catch with their suctorial feet, and retain opposite the mouth by means of the spinous projections surrounding it. We have found in their stomachs various univalved species, but the conchifera are supposed to be more especial favourites. M. Eudes Deslongchamps has observed five or six individuals of Asterias rubens clustered together in the form of a ball, the nucleus of which was a Mactra. The star-fish had retroverted their vesicular stomachs, and were found endeavouring to suck out the fish from between the valves of the shell; but it is impossible to believe, with this naturalist, that the Asterias had separated, or were capable of separating them, so as to inject within a fluid capable of benumbing the mollusc and placing it beyond resistance, the more especially as this fluid has no other than imaginary existence. There can be no doubt that the valves had partially opened, from the feebleness or death of the molluscum, before it was set upon by the star-fish.[3] We have seen similar clusters around a Turbo or whelk. Deslongchamps's opinion is indeed only worth notice as coinciding with that of the fishermen, who, regardless of the certain inefficiency of the agent, are fond of telling of the exterminating war waged by the Asterias against the oysters; a tale which has its invention at a far-distant date, being found in Aristotle, paraphrased by Ælian, and versified by Oppian, and hence copied without question by every subsequent popular compiler.

In their turn the Stellerides are greedily preyed upon by fish of almost every sort; for they who assert that the acridity of their flesh, or the spines and prickles of their skin, render them distasteful or formidable,[4] know nothing of the voracity and power of their foes. We have very often found the stomach of cods and haddocks crammed with the remains of star-fish, more especially of the prickly Ophiuræ, and that at a season when the fish were in high perfection. Dr Knox has attempted to prove that the ova of the Echinodermata are the proper food of the salmon, which is only fit for the table of the epicure when he has been feeding on them: "from the richness of the food on which the true salmon solely subsists, arises, at least to a certain extent, the excellent qualities of the fish as an article of food."[5] Vast numbers are more certainly destroyed by the fisherman, who finds they materially injure the produçe of his art, by clinging to and clustering round his baits, and who therefore wreaks his vengeance on them by throwing them in heaps on the dunghill. In some places the common species have even been used as manure; but otherwise man has not found them adapted to his use, for the medicinal virtues which the early physicians and astrologers ascribed to them, have disappeared in their modern generations.

To remedy that looseness of description which of necessity belongs to such general views as we have been giving, we proceed to notice the systematic arrangements of the order, whose only common characters seem to be, as Linck long ago observed, a depressed multifid coriaceous body, with rays or lobes radiating from the margin of the disc, and an inferior central mouth. Linck's primary division of it into the fissured and entire (fissæ et integræ) indicates his perception of those differences in structure on which modern naturalists found their principal families; but his want of knowledge of system becomes very obvious in the subordinate details, when he exclusively drew the character of his secondary divisions from the number of the rays; a character of such trivial importance as not even to be specifical, but subversive of every natural affinity. Linnæus arranged the whole under one genus (Asterias); which Lamarck divided into four, whose essential characters may be shortly stated thus:

* Rays articulate, distinct from the disc.

1. Comatula. Rays of two kinds, dorsal and marginal; the dorsal simple, short and filiform; the marginal larger, and pinnate.
2. Euryale. Rays marginal, alike, dichotomous, and much divided.
3. Ophiura. Rays alike, marginal and simple.

** Rays continuous with the disc.

4. Asterias. Rays furrowed underneath, and tentaculiferous.

Cuvier adopted the genera of Lamarck, but, with a proper regard for the rights of priority, for Comatula he substituted the name *Alecto*, and for Euryale that of *Gorgonocephalus*, which had been previously bestowed on the same groups by our celebrated countryman Dr Leach. The genus Ophiura, Cuvier further proposed to divide into two; the one embracing those species whose rays are furnished with mobile lateral spines, and between whose articulations small fleshy tentacular filaments (*pieds*) issue on each side; the other those in which the rays, having no lateral spines, resemble the tails of lizards. In these "the central disc has, in each interval of the rays, on the side where the mouth is, four holes, which penetrate into the interior, and serve perhaps for respiration, or, according to others, for the issue of the eggs. There are no feet, except in five short furrows, which form a star around the mouth." The genus Encrinus, which Lamarck had referred to the Zoophytes, Cuvier properly placed near the Comatula, adopting the views of Miller implicitly in regard to its structure and further subdivisions.

Miller names the family of which the Encrinus may be considered the type, *Crinoidea* or lily-shaped animals, a family rendered interesting, as Mr Parkinson[6] remarks, not only by their curious forms and extraordinary structure, but also by their being among the earliest inhabitants of this planet. Hence they are so far aliens of this world, that whilst immense tracks of rocks are literally formed of the entombed remains of different species in a mineralized condition, only five or six species have yet been discovered in a recent state.[7] "An idea of their structure may be obtained if we imagine an Asterias placed with its mouth upwards on a columnar jointed stem, one end of which is connected to the dorsal surface of the animal, and the other most probably fixed at the bottom of the sea. The rays or arms extending from the circumference of the body are much branched, and at last pinnated; other jointed processes, named auxiliary arms, surround the stem in whorls placed at short intervals. The column is perforated in its centre with a narrow canal, down which a prolongation of the stomach extends, and lateral canals proceed from the central one through the verticillate auxiliary arms The Comatula has rays spreading from the circumference of the body, branched and pinnated like those of the Pentacrinite. It is not fixed on a column, but the dorsal surface of the body is elevated in the middle. and bears a number of smaller rays or arms; and this dorsal eminence, with its rays, has been sometimes compared

Echinodermata.

to a rudiment of the column of the Pentacrinite with its auxiliary arms. Besides the mouth, there is an anal opening on the ventral surface, situated on an eminence near the margin."[1] The exactness of the comparison here drawn between the Comatula and Pentacrinus, first detected by the acuteness of Miller and Gray, has been singularly illustrated by the discovery of Mr J. V. Thompson, that Pentacrinus is only Comatula in its first stage of existence; the head, in the progress of development, separating from the stem, to become, instead of a fixed pedicellated floriform zoophyte, a nomade star-fish in the bosom of the ocean. In their fixed condition, the Crinoidea appear to have had a considerable range for the seizure of their prey, without possessing absolute locomotion,

> Still moving, yet immoved from their sted;

for the peculiar mode of the articulation of their vertebræ probably afforded them a great degree of mobility, with considerable security against dislocation.[2] They grow erect, the stem being in general sufficiently stiff and strong to support the heavier head; but when it is not so, as in the Umbellularia, we find that, just under what has been called the pelvis, "a hollow bladder-like membrane" embraces the upper part of the stalk for about two or three inches, and, performing the office of a buoy or swimming-bladder, keeps the head in an upright position.[3]

In 1826, Mr J. E. Gray proposed to divide the Stellerides into three families. I. *Asteriadæ*, distinguished by having tentacular feet in the ambulacra of its rays, and by a calcareous wart (the *corpus spongiosum* of Spix) on the dorsal surface of the disc: II. *Ophiuridæ*, with solid articulated rays, and no wart: III. *Encrinidæ*, co-equal with the Crinoidea of Miller, and distinguished from the two preceding by possessing a double aperture to the digestive organs, a peculiarity which he was the first to discover in Comatula.[4]

Our limits will permit us to give no more than a mere outline of Blainville's arrangement, which rests on the same basis, but is more elaborately framed, and embraces the crinoidean genera, which the industry and sagacity of Miller had enabled him to detect and define.

Body

Agassiz has not introduced any essential novelty in the distribution of this family, but, to compensate the brevity of our notices of previous attempts, we find it necessary to give the definitions of such of his genera as contain recent species, at length.

FAMILY I.—ASTERIADÆ.

The Asteriadæ answer to the limits which Lamarck has assigned to the genus Asterias. What distinguishes them is their possessing a single orifice of the intestinal canal, surrounded by suckers, but void of teeth; while deep grooves, containing several series of pedicles, extend from the mouth to the extremity of the rays. On the dorsal surface we remark, between the two posterior rays, a calcareous wart, convex externally, and grooved like a madrepore, which has therefore been denominated the madreporiform tubercle. It covers a singular organ, named the stone-canal by Tiedemann, who believed its office to be the secretion of the earthy matter required for the growth of the calcareous skeleton. The accuracy of his description of its structure has however been called in question; and the opinions relative to its function are various and contradictory.[7] Blainville considers it to be in some way connected with generation; and from its variations he asserts we may draw our most permanent characteristics of the species.[8] It is almost certain, he also tells us, that there is a distinction of sexes among them, and consequently a sexual union; and indeed Otho Fabricius says that in the month of May in Greenland they are to be found in pairs united face to face.[9]

Genus Asterias, *Linn.*—Body star-like; superior surface tesselated; rays flattened, edged with two series of large laminæ bearing small spines.

Genus Cælaster, *Ag.*—"Differs from the preceding genus in having the interior cavity circumscribed by laminæ arranged like those of the Echini, and at whose summits we observe a star of ambulacra. This genus approaches therefore by its organization to the family of the Crinoïdea, while its form is that of the true Asteriæ." There is only one fossil species.

Genus Goniaster, *Ag.*—"Body pentagonal, bordered by a double series of laminæ, bearing small spines; upper surface nodose."

Genus Ophidiaster, *Ag.*—"Body star-like, finely tesselated on its whole surface; inferior grooves very narrow."

Genus Cribella, *Ag.*—"Body star-like, rays tuberculous and elongated; epidermis porous in the intervals."

Genus Uraster, *Ag.*—"Body star-like, entirely covered with more or less prominent spines."

Genus Asterina, *Nardo.*—"Body pentagonal, covered with pectinated scales; upper surface inflated; grooves of the under surface deep."

Genus Palmipes, *Linck.*—Body pentagonal, very flat, thin, but membranaceous at its edges.

Genus Calcita, *Ag.*—Body pentagonal, slit at the angles; teguments granular.

FAMILY II.—OPHIURIDÆ.

The Ophiuridæ are distinguished by the central part of their body forming a distinct and flattened disc, to which are annexed more or less elongated and even ramified rays, with no grooves on their surface. "They are *spinigrade* animals, and have no true suckers by which to walk, their progression being effected (and with great facility) by means of five long flexible jointed processes, placed at regular distances round the body, and furnished with spines on the sides and membranous tentacula. These processes are very different from the arms of the true star-fishes, which are lobes of the animal's body; whereas the arms of the Ophiuridæ are superadded to the body, and there is no excavation in them for any prolongation of the digestive organs. The stomach is a sac with one aperture, its walls externally covered with vibratile cilia. The ovaries are not branched; they are placed near the arms, and open by orifices near the mouth, between the origin of the arms. Their investing membrane is also ciliated; but on the rest of the body and arms no cilia exist, hence we may conclude there is no separate respiratory system."—*Edward Forbes.*

Genus Ophiura, *Lam.*—Disc much flattened; rays simple, squamose, bearing very short spines adhering to the rays.

Genus Ophiocoma, *Ag.*—This genus differs from the preceding in having very long moveable spines attached to the rays.

FAMILY III.—CRINOÏDEA.

The Crinoïdea, notwithstanding their star-like form and their great external resemblance to the Ophiuridæ, constitute however a distinct family, characterized by the presence of two separate orifices to the intestinal canal, although very near to each other. These orifices are by no means easily distinguished among the rays which surround them, especially in the fossil species. The greatest part of the species are pediculate, *i. e.* carried on a foot-stalk adhering to the centre of the region, which, in the star-fish, we considered as the middle of the dorsal surface.

Genus Comatula, *Lam.*—Disc pentagonal, arched at its upper surface, which bears several series of simple and articulated rays; rays of the disc bifurcate, beginning however with two simple pieces. The edges of the rays are pinnate; mouth central, sunk; anus between the mouth and the border of the disc, obliquely prominent. Animal free when mature, but fixed and pedicellate when young.

Mr J. V. Thompson has discovered that "the body of the Comatula, when the animal is kept in a small quantity of sea-water, is soon detached, entire and perfect, from the cavity in which it is lodged, and in this state it might be mistaken for an animal of a very different tribe." He suspects that the genus *Mammaria* of Müller may have no better foundation. The same naturalist has made the still more singular discovery that the Pentacrinite of the Irish seas, which he first described under the name of *Pentacrinus Europæus*, and which has since been made the type of the genus *Phytocrinus* by De Blainville and Agassiz, is a Comatula in its earlier states of development. When not more than one eighth of an inch in height, this Pentacrinus "resembles a little club, fixed by an expanded basis, and giving exit at its apex to a few pellucid tentacula; no other part of the solid fabric is observable, but an indistinct appearance of the perisome. In those specimens which have made a little more progress, together with the elongation of the pedicle or stem, its joints begin to make their appearance; the body acquires a larger size and brownish tint, from a grosser food; the tentacula of the mouth protrude in a greater degree, and move slowly in various directions. In others still more advanced, the joints of the stem become quite obvious, from their opacity and white colour, and the base of the future arms, as well as the auxiliary side-arms, are rendered palpable. The arms from this period lengthen apace from their bifurcation, and have superadded to them a double range of transparent jointed tentacula; so that the animal begins to put on a more perfect appearance, and now for some time merely acquires a somewhat greater size and an extension of its arms, which, although they solidify from their origin upwards, remain pellucid and thick at their apices, where elongation, evolution, and the secretion of calcareous matter is gradually going on." Subsequently the arms again bifurcate at or near to their extremities, a second and even a third time, and having reached the full development entitling it to the name of a Pentacrinite, the head appears to be cast off, that it may become a nomade Comatula. How just then the conclusion of Mr Thompson from these interesting discoveries. "From these observations connected with the growth of this animal, and by which it appears to present itself at various stages of its progress under considerable diversity of form, naturalists may learn to avoid the unnecessary multiplication of the genera and species of the Crinoïdea, by giving undue weight and consideration to characters originating in the progressive evolution of individual species, and which are consequently of a transitory and delusive nature."[1]

[5] These are sub-genera or sections only of the genus Asterias.

[6] *Man. d'Actinologie*, p. 235.

[7] The subject is ably stated by Dr Sharpey in *Cyclop. of Anat. and Physiology.*

[8] *Man. d'Actinologie*, p. 237.

[9] *Man. d'Actinologie*, p. 236.

Genus Comaster, *Ag.*—This genus has the same organization as the preceding, but the arms are ramified instead of being simply furcate.

Genus Ganymeda, *Gray.*—The genus which Mr Gray described under this name in the *Proc. Zool. Soc. of London* for 1834, p. 15, he has ascertained to be founded on what is evidently only the basal joint of the body of the English species of Comatula.—*Annals and Mag. of Nat. Hist.* i. p. 158.

Genus Pentacrinus, *Miller.*—Pedicle more or less pentagonal, bearing at intervals simple verticillate rays; rays of the disc fixed to the pedicle, each by a cuneiform piece, followed by two simple pieces, after which the rays bifurcate, and at a little farther distance divide into two, which then branch out into numerous appendices, pinnate at their edges. The space between the base of the rays, occupied by the visceral cavity, is formed by numerous small laminæ. The only living species (*P. caput Medusæ*) is a native of the Carribbean seas.

III.—ACALEPHÆ.[2]—SEA-JELLIES.

The Acalephæ have been named by Blainville the *Arachnodermata*, to mark in a stronger manner how remarkably they contrast with the *Echinodermata* in the structure of the skin, which is a soft serous pellucid cuticle, containing sometimes miliary granules, but always smooth and even, and as thin as the gossamer's web. They are radiated animals of a gelatinous consistency, with an unarmed mouth in the centre of the ventral surface, the entrance into a stomachal cavity without proper parietes, but furnished with vasculiform canals ramified through the body; their respiratory apparatus is ciliary, and their mode of generation oviparous; they are all nomade and marine, and move through the water by alternate contractions and dilatations of their periphery, or by the aid of vibratile cilia. The constituents of the class are divisible into two orders, viz., 1. The Medusides, with a body almost always circular, convex dorsally and concave below, supported in a few genera by an internal cartilaginous plate; the rim, as well as the oral aperture, mostly fringed with tentacular ciliated appendages: 2. The Acalephes properly speaking, whose body is irregular and multiform, bilateral, and sometimes orbicular, with brachial or filamentous appendages, and ciliary fringes.

ORDER I.—MEDUSIDES.[3]

Among animate creations, there is none that excels the Medusides in beauty and ornament, or in the variety and eccentricity of their forms;

> ———————— there's not a gem
> Wrought by man's art to be compared to them;
> Soft, brilliant, tender, through the wave they glow,
> And make the moonbeam brighter where they flow.

When floating in the ocean, most of them appear like crystal bowls of the purest transparency, veined and patterned with the most brilliant colours, and their rims ornamented with fringes, furbelows, and arbuscles of such delicacy and intricacy of workmanship, that even the most experienced in nature's works marvel how it is that such textures, too frail to bear the lightest handling, are kept entire amid the restless element of their nativity.[4] We have often watched with intense interest some of the least complicated, and, it may be, some of the least beautiful, as they floated by us on the surface of a summer's sea. On a hasty examination, they may seem to be supported there by their own inherent buoyancy, and to be carried onwards with the tide or current, which they have apparently no power to resist; but watched a while, they are seen alternately to contract and expand the whole periphery of the body at regularly-timed intervals, in a manner which Dr Roget has aptly illustrated by comparing it to the opening and shutting of a parasol, and with a quickness and force which we have felt to be considerable. By these motions the Medusides can swim against a gentle current, though they more commonly yield themselves up to its persuasive violence; and when alarmed they can also sink deep into the bosom of the sea with considerable velocity, so as frequently to elude an attempt to secure them. They can stop and maintain themselves at any depth, and rise again with equal ease to enjoy a nearer intercourse with light and air. Lamarck's speculations rendering it necessary to deny to them either nerves or muscles, he has persuaded himself that these motions of the body are entirely mechanical, produced by the influx and efflux of imponderable fluids, such as electricity, permeating and flowing through its gelatinous texture;[5] but we are very sure that he will summarily reject this theory who has once observed the phenomena, which are certainly in some degree under the control of the animal, and regulated by its will and sensations. It seems indeed to be now proved, more especially by the anatomies of Ehrenberg,[6] that they are the effects of the contraction of muscular fibres, radiating from near the centre of the body to the circumference, running alongside the vein-like nutritious canals, and by others in the rim, which have a circular direction. We know also that the Medusides do possess a nervous system, formed after the same plan, and rather more complete than it is in other radiated beings.

The figure of the Medusides is regular and almost always circular (for the Velella alone are oval), sometimes discoid or spheroidical. but generally hemispherical, so as to allow of a comparison between them and the mushrooms, which they are presumed to represent in the animal kingdom; and the

Acalephæ.

same fancy may see in them the living models on which our umbrellas have been made. The margin is usually fringed with tentacular filaments; and in many species we also observe, placed at wide intervals, a circle of coloured warts, which, from their organization, are evidently organs of importance in the animal's economy. Ehrenberg believes them to be branchial, for connected with each of them he has discovered a partial circulation of a fluid analogous to blood; and, what is still more singular, he has detected in their near vicinity an organ retractile, within a sheath, and containing a mineral crystal, to which he assigns the office of an eye, because it is similar in structure to the eye of several infusory animalcules, and is more amply provided with nerves than any organ other than one of sense ought to be.

The under surface of the umbrella is sometimes entirely naked, sometimes furnished with numerous scattered tentacular suckers, as in Porpita and Velella, or with greatly diversified brachial appendages, which depend usually from the lips of the mouth. These are either free from each other and separate to the base, or they coalesce so as to form a kind of stalk previous to their ramification into lobes or filaments, each division having at its extremity pores for the absorption of the thin nutriment on which such species must necessarily subsist. The Medusæ with this structure resemble a bulbous root with its radical fibres, and were therefore called *Rhizostomous* by Cuvier.[1] The greater number of the Medusides, however, have a distinct mouth, placed always centrally, either sessile or at the end of a species of proboscis more or less prolonged. It has no hard parts, nor teeth, nor jaws, and leads by a very short œsophagus into the stomach, consisting frequently of four separate cavities excavated in the gelatinous parenchyma, without any peculiar lining. From the stomach proceed numerous vessels, which all bend to the circumference. Some of these vessels are simple and undivided, others ramify dichotomously like veins, and form anastomoses among their ultimate divisions. Injections from the stomach pass more readily into the simple than into the ramose vessels; but both kinds serve for the conveyance of the digested food, whose unassimilated remains pass from the body through their extremities, which open by apertures on the rim. The portion intended for nutrition and growth probably transudes in part into the parenchyma, while it flows along the vessels; and a part seems to enter a peculiar vessel which runs round the periphery that it may pass into the partial circulations at the marginal tubercles, and be submitted to the action of the air. It must, however, be admitted that these tubercles exist in comparatively few species;[2] and there can be little doubt that the principal airing of the nutritive fluids is effected by the action of the circumfluent water on the exterior surface, as well as in the internal cavities and vessels. To effect this great purpose the more completely, we find that the oral and marginal filaments are clothed with vibratile cilia, which drive currents of water over them in determinate directions; and these cilia are said likewise to line some of the interior cavities. It is from their action that portions cut off from the appendages continue to move like independent and perfect beings; a circumstance apparently so demonstrative of their completeness, as to have given origin to several spurious species.

The Rhizostomes, as we have already mentioned, feed only on fluid matters, and such also is the condition of those genera which Peron and Le Sueur named *agastric*, from a belief that they had neither mouth nor alimentary sacs; for although this latter statement has been shewn to be erroneous, yet the absorption of the aliment appears to be through pores. But the bulk of the Medusides love a grosser fare, and there is some slight evidence in favour of their having a discrimination in the matter; for Gaede remarks that he has never found fishes in the stomach of Medusa capillata, but often worms; while in that of Medusa aurita there are frequently fishes, rarely worms. The latter species, according to our observation, feeds more frequently on pelagic Gammari; and minute crustacea and entomostraca constitute the principal food of most of them. Digestion is extremely rapid. We remember once observing in the stomachs of Medusa aurita, several specimens of a Gammarus unknown to us,[3] and which we were anxious to examine: they were living when first seen, and when we left the Medusa in a basin of sea-water for half an hour, we little dreamed of the disappointment awaiting our return, for not a trace of the crustacea was then visible.

Acalephæ.

All the species are propagated by ova generated in appropriate organs situated generally in the immediate vicinity of the stomach, but very variable in appearance and general structure. Previously to the deposition of the spawn, the ovaries swell in a very remarkable manner, and the young Medusæ, according to Blainville, are cast out through the mouth, sometimes after a certain degree of development in the appendages. In the Medusa aurita, according to Ehrenberg, the ova, previously to their maturation, escape through the peculiar aperture of the ovarial sac into the water, where they are laid hold on by the tentacula and the two layers of the brachial appendages, and received into little sacs which are formed on these layers, and which have a direction from the interior outwards. It is in these sacs that the ova are metamorphosed and matured. While in the ovary they have a thin smooth membranous envelope, are of a roundish figure, and filled with a dark-violet granulous fluid; but in the fœtal sacs they have no shell, and present themselves under three distinct forms. Some resemble bramble-berries, and their colour is a pale violet; others, also of a pale violet, are disciform, in shape like a miniature Medusa, without arms, and without nutritive canals; and the third, which is the most numerous, has a cylindrical form, truncated at both ends, and of a yellowish-brown tint. The last two are densely covered with cilia, and swim freely. The largest among them attain a diameter equal to the one eighth of a line; and they are about one third of this size when they lose their shell. From being unable to discover male organs in this Medusa, Ehrenberg has hazarded the conjecture that the smaller ova may become, as we understand him, males, which remain always of a microscopical size, while the females only grow large;[4] but the conjecture is a bold one. We are scarcely able to reconcile these interesting facts with one observed by M. Saars. In a small volume published some years ago, this Swedish naturalist described a new genus of Medusides under the name of *Strobila*, from its great similitude to a fir cone; but he now assures us that the Strobila is the young of M. aurita. In its strobiline state, it is composed of a series of circular pieces, with numerous tentacula, and the cone is surmounted by a cylindrical shaft: in its development the pieces separate successively into disciform ra-

[2] We may here warn the student that he should guard against the too great extension of these general remarks; for the truth is, few species have been examined anatomically, and even the most general detail will be found to have many individual exceptions.

[3] Probably the Oniscus medusarum of O. Fabricius. *Faun. Groenl.* p. 257.

[4] *Ann. des Sc. Nat.* n. s. iv. p. 297. Rathke apparently borrows his account of the development of the Medusæ principally from Ehrenberg, but he omits their escape into the sea previously to their introduction into the brachial sacs, which is really incredible; and he says that when lodged in these sacs they have no longer a chorion, as Ehrenberg pretends, and are consequently already young Medusæ. See Burdach's *Traité de Physiologie*, tom. iii. p. 67, &c.

Acalephæ.

diated fragments, each of which becomes a perfect individual.[1]

The growth of the Medusides is as rapid as their life appears to be short and transitory. There are many which never reach the magnitude of a pin's head; and thence they graduate upwards to a size, even in our northern seas, of fully two feet across the disc, with labial appendages not less than six feet in length. The bulk to which they occasionally grow in the Indian Ocean is immense; and were a like hugeness attainable by them in the northern seas, we might lend an easy belief to those naturalists who tell us that the *Kraken* was truly a Medusa.[2] Mr Telfair saw a Medusa cast on shore in the Bombay territory in 1819, which must have weighed many tons. "I went to see it when the gale had subsided, which was not for three days after its being cast upon the sand; but it had already become offensive, and I could not distinguish any shape. The sea had thrown it high above the reach of the tide, and I instructed the fishermen who lived in the immediate neighbourhood to watch its decay, that if any osseous or cartilaginous part remained, it might be preserved; it rotted however entirely, and left no remains. It could not be less than *nine months* before it entirely disappeared, and the travellers were obliged to change the direction of the road for nearly a quarter of a mile to avoid the offensive and sickening stench which proceeded from it."[3]

The Medusides abound in our seas during the summer and autumn, and are thrown ashore in heaps after every storm.[4] Before the winter has set in, they have disappeared, most of them being doubtless destroyed; but during the cold season some surely inhabit the deep recesses of the ocean, to re-appear in another season; and it is probable that the spawn of one summer's generations lies hidden in the ooze until revived and evolved by the heat of the coming summer. In tropical seas they are still more profuse, as well as more sportive in their configurations. Voyagers tell us of sailing through flocks so dense as to check the ship's progress, and expanding for miles over the surface; nor are they weary of speaking of their beauty and their phosphorescent and stinging properties. In the arctic seas these creatures are equally abundant, furnishing the giant whale with the material of his growth, and swarming so thick, when of microscopic minuteness, as to communicate their colour to the water. After his description of a globular semi-transparent species, from 1-20th to 1-30th of an inch in diameter, Dr Scoresby proceeds to say, "I afterwards examined the different qualities of sea-water, and found these substances very abundant in that of an olive-green colour; and also occurring, but in less quantity, in the bluish-green water. The number of Medusæ in the olive-green sea was found to be immense. They were about one fourth of an inch asunder. In this proportion, a cubic inch of water must contain 64; a cubic foot 110,592; a cubic fathom 23,887,872; and a cubical mile about 23,888,000,000,000,000. From soundings made in the situation where these animals were found, it is probable the sea is upwards of a mile in depth; but whether these substances occupy the whole depth, is uncertain. Provided, however, the depth to which they extend be but 250 fathoms, the above immense number of one species may occur in a space of two miles square. It may give a little conception of the amount of Medusæ in this extent, if we calculate the length of time that would be requisite, with a certain number of persons, for counting this number. Allowing that one person could count a million in seven days, which is barely possible, it would have required that 80,000 persons should have started at the creation of the world, to complete the enumeration at the present time."[5]

Great numbers, for all of them are not so, as has been asserted, of the Medusides, are phosphorescent animals, emitting their lights at irregular intervals; and the flame generally passes away after a short glow. The large species appear, when luminous, like globes of living fire floating on the surface, or shining at a great depth through the water; but when the species are small and crowded, the luminousness is diffused all round, or it is broken into innumerable spots of light, "rising to the surface, and again disappearing, like a host of small stars dancing and sparkling on the bosom of the sea."[6] The first kind of light is at least sometimes emitted at the pleasure of the creature, without the intervention of any foreign irritation;[7] but the other two seem always to require for its elicitation some outward stimulus, such as is given by their mutual contact and friction when a fresh breeze curls the waves, or when an oar-driven boat or a ship passes through the teeming waters, when "a long train of lambent coruscations are perpetually bursting upon the sides of the vessel, or pursuing her wake through the darkness."

In such species as we have observed, the luminosity could not be detected issuing from any particular point or organ: it seemed that the whole body was impregnated with the light, which was given out involuntarily, if we may so speak; for some exterior irritation was necessary to produce the appearance of it, though the Medusæ do not distinguish whether the annoyance proceeds from an animate or inanimate object. The species which possess the property are diffused through all seas, and the phenomenon is little less beautiful and interesting in the Hebrides than it is under the line, or in Australian seas.[8] "The phosphorescence takes place, particularly around the tentacula, during the movements of the animal. Macartney saw it increased in the Medusa lucida when he warmed the water. The light also became more vivid in alcohol; the animals, however, quickly perished in it, and their light was extinguished. Spallanzani remarked the trickling of a viscous fluid from the surface of Medusæ, which had a burning taste, and produced an itching sensation on the skin. This liquid, mixed with water or milk, renders them phosphorescent for some hours, particularly when they are warmed and agitated. Dead animals, whose light was extinguished, again became phosphorescent by the addition of a quantity of spring water, and by movement at a heat of 26° to 37°. Humboldt observed his fingers to shine for some time after he had touched Medusæ: he also saw the light become stronger when the animals were galvanized. The light of Medusæ to which Macartney applied an electric shock, was extinguished for an instant, but afterwards appeared more vividly than previously."[1] In reference to the immediate cause of the phenomenon, the opinions which have been divulged are numerous and contradictory: here it must suffice to give Tiedemann's, as the most probable. "Weighing well all the circumstances," says he, "phosphorescence would seem to depend on a matter, the product of the changes of composition accompanying life, and, to all appearance, secreted from the mass of humours by particular organs. This liquid probably contains phosphorus, or an analogous combustible substance, which combines with the oxygen of the air, or of aerated water, at a medium temperature, and thus produces the disengagement of light. The preparation and secretion of this substance are acts of life, which change, augment, or decrease by the influence of external stimulants, whose action on the animals modifies their manifestations of life. But the phosphorescence itself depends on the composition of the secreted matter, and cannot be regarded as a vital act, because on certain occasions it continues for whole days, even after the death of the animal."[2] As for its use, opinions are equally various; but perhaps we err least when we conjecture it may serve to protect those gifted with it from the aggressions of their enemies.

---

[1] *Ann. des Sc. Nat.* n. s. vii. p. 248.

[2] See Baster, *Opusc. Subs.* i. p. 26.

[3] *Edin. New Phil. Journ.* iv. p. 406.

[4] "They are sometimes thrown in great quantity upon the shores of our climate, where endeavours have been made to turn them to some advantage. It has been attempted, but without much success, to extract ammonia from them. They have been more beneficially employed in the way of manure upon arable land." Griffith's *Cuvier*, xii. p. 567. The Medusides are all pelagic; but Professor Schwencke is said to have kept a species for six days alive in a basin of *fresh* water,—"ex Spara fluvio hausta."—a very wonderful fact, when we remember how instantaneously poisonous fresh water is to marine animals in general. Baster, *Opusc. Subs.* ii. p. 58.

[5] *Edin. Phil. Journ.* ii. p. 12.

[6] Baird in *Mag. of Nat. Hist.* iii. p. 309, and vol. ix. p. 502. See also Thompson's *Zoological Researches*, p. 38, &c.

[7] Some naturalists deny the luminous property of the Medusides *ex toto*, maintaining that the light is merely elicited by friction, &c., from some matter or fluid with which the water is impregnated at the time. This opinion is ably supported by Mr Westwood in the *Mag. of Nat. Hist.* iv. p. 505, &c.; and for some observations confirmatory of this view, we refer to the same work, vol. v. p. 1, &c. The opinion however appears to us to be untenable, and is apparently disproved by the fact that Medusæ have been noticed giving out their light at many fathoms depth, where they were beyond disturbance. "While sailing in the more shallow parts of the Carribbean Sea," says the Rev. Mr Guilding, "and looking over the vessel's side when becalmed in these dangerous waters, in the midst of reefs, I have seen at the bottom huge molluscous or radiate animals emitting the splendour of a lamp, but could never ascertain the species." *Mag. of Nat. Hist.* vii. p. 581. It were easy to quote similar facts, but a more conclusive one is this. We had a luminous Dianea in a glass of sea-water, and in a vessel of the *same water* we had, at the *same time*, a small specimen of Medusa aurita. The light was readily evoked from the Dianea, but we could obtain no light from the other vessel. It must therefore have proceeded from something else than the water. See in relation to this question the observations of Mr Bennett in *Proceedings of the Zool. Soc. of London* for January 1837; and those of his brother in the same work for June 13, 1837.

[8] This is contrary to the assertion of voyagers, and it may be that our opinion is biassed by our partiality to all that is native. Humboldt says, "The sea is phosphorescent in all latitudes; but he who has not witnessed this phenomenon in the torrid zone, and especially in the Pacific Ocean, can form but an imperfect idea of the magnificence of such a spectacle." See *Edin. New Phil. Journ.* v. p. 329.—Dr Macculloch, during a voyage to the Shetland and Orkney Isles, discovered upwards of 190 luminous animals, of which the most conspicuous were about twenty small Medusæ. *Edin. Phil. Journ.* v. p. 389.

Many Medusides possess likewise a stinging property sufficiently strong to blister the skin and inflict acute suffering.[3] Bosc describes the consequences thus. When a venomous Medusa touches the skin, there results a considerable redness, with buttons of the same hue, which have a little white spot in their centres, attended with a piercing pain, which, after it has somewhat subsided, may be compared to often-repeated pricks. This lasts generally a half hour, and may be appeased by the application of linen steeped in oil, or even in fresh water. The redness will often re-appear after the lapse of several days, when the part is exposed to a temperature higher than that of the atmosphere.[4] He imagined that it was occasioned by the application of numerous microscopical suctorial papillæ, which issue from the surface of the tentacular arms, to the skin; but this is disproved by the fact of the dead animal being not less vesicatory than the one yet living. It probably resides, as Dicquemare believed, in some caustic exudation of the exterior membranes; but it is not identical with the phosphorescent secretion, for some vesicating Medusæ are not luminous, and we know from our own experience that our native luminous species are not all endowed with the power of vesication.

The distinction of the species is difficult, because of the changes which they suffer in their growth; and the difficulty is increased by their frequent minuteness and transparency, which render them scarcely visible in the water; by their soft fragility and tendency to dissolution, which prevents them being handled without injury, and opposes an almost insurmountable obstacle to their preservation in museums. From these inherent difficulties, the classification of the Medusides is believed to be still in an imperfect and artificial state; yet a comparison between its Linnæan barrenness, when one small genus embraced all the known species, and its present richness, when many genera are necessary to exhibit all its variety and fulness, affords a pleasing argument in behalf of the zeal and inquisitiveness of modern naturalists. Peron and Le Sueur, with a good knowledge of what had been done by others, and with much new information acquired in their voyages, were the first to attempt the orderly arrangement of the Medusides;[5] but it was found to be too artificially constructed, and has not been adopted by subsequent systematists. Lamarck's method, which was based on Peron and Le Sueur's, has the recommendation of greater simplicity. It is as follows:

RADIARES MEDUSAIRES.

* *One mouth only in the inferior disc of the umbrella.*

1. Umbrella without pedicle, or arms, or tentacula.
   - [*a*] No lobes or appendages on the margin of the umbrella.
     Eudora. Phorcynia.
   - [*b*] With lobes or appendages on the margin.
     Carybdea.
2. Umbrella without a pedicle, and armless, but furnished with tentacula.
   Equorea.
3. Umbrella without a pedicle, but with arms[6] below, and generally with tentacula on the margin.
   Callirhoe.
4. Umbrella with a pedicle, with or without arms. No tentacula at the margin.
   Orythia.
5. Umbrella with a pedicle, with or without arms: tentacula on the margin.
   Dianea.

* * *Several mouths in the inferior disk of the umbrella.*

1. Umbrella without pedicle, arms, or tentacula.
   Ephyra.
2. Umbrella without a pedicle or arms, but with marginal tentacula.
   Obelia.
3. Umbrella without a pedicle, but furnished with arms underneath. No marginal tentacula.
   Cassiopea.
4. Umbrella without a pedicle, but with arms underneath, and marginal tentacula.
   Aurelia.
5. Umbrella having a pedicle and arms, but no marginal tentacula.
   Cephea.
6. Umbrella having a pedicle and arms, and marginal tentacula.
   Cyanea.[7]

The following table gives a synoptical view of the system adopted by Eschscholtz in his work on this order,[8] which has a high reputation, and is founded on much personal observation.

1. M. Discophoræ.

Medusæ with a large central digestive cavity, and for their only locomotive organ a gelatinous disc in form of an umbrella, constituting the greater part of the body.

Section 1.—PHANEROCARPÆ.

The ovaries are visible.

Family 1st. Rhizostomidæ......	Cassiopæa. Rhizostoma. Cepnea.
Family 2d. Medusidæ....	Sthenonia. Medusa. Cyanea. Pelagia. Chrysaora. Ephyra.

Section II.—Cryptocarpæ.

The ovaries are concealed.

Family 3d. Geryonidæ.......	Geryonia. Dianæa. Linuche. Saphenia. Eirene. Lymnorea.
Family 4th. Oceanidæ........	Oceania. Callirhoe. Thaumantias. Tima. Cytacis. Melicerta. Phorcynia.
Family 5th. Æquoridæ....	Æquorea. Mesonema. Ægina. Cunina. Eurybia. Polixena.
Family 6th. Berenicidæ...	Eudora. Berenice.

Blainville divides the class into two very unequal sections, from the presence or absence of a solid plate of support to the soft gelatinous umbrella or body of the animal,—the *Cirrhogrades* having such a support, and the *Pulmogrades* being destitute of it; and they are further distinguished by considerable differences in the nature of the appendages which garnish the oral surface. The Pulmogrades, by far the most numerous in its constituency, and embracing the proper Medusides, might be divided into perhaps natural subsections by the character of their digestive organs; some having no mouth or stomach, as has been alleged, and others having a distinct stomachical cavity, with one or more oral apertures. But Blainville prefers drawing the distinctive peculiarities of the families from the form and appendages of the mouth, or central part of the disc; for he thinks it very doubtful whether any among them are really unfurnished with a stomach, a fact which is anomalous in the animal kingdom, and which every subsequent observation tends to disprove. He gives the following synopsis of his system, which embraces all the genera of Peron and Le Sueur, and of Eschscholtz; but he tells us at the same time that he doubts the existence of several of them, for they seem to be founded on imperfect figures, perhaps representing parts only of some mutilated species.

Sub-order I.—Pulmogrades.

Section i. *Simple.*—Eudore : Ephyre : Phorsynie : Eulymene : Carybdee : Euryale.

Section ii. *Tentaculated.*—Berenice : Equoree : Mesoneme : Polixene : Ægine : Cunine : Foveolie : Eurybie : Pegasie : Obelie.

Section iii. *Subproboscidiform.*—Oceanie : Aglaure : Melicerte : Cytacis : Thaumantias : Tima : Campanella.

Section iv. *Proboscided.*—Orythie : Geyronie : Saphenie : Dianee : Linuche : Favonie : Lymnoree : Sthenonie.

Section v. *Brachiated and pedunculated.*—Ocyrœ : Cassiopee : Aurelie : Melitee : Evagore : Cephee : Rhizostome : Chrysaore : Pelagie.

Sub-order II.—Cirrhogrades.

The genera are, Velelle : Rataire : Porpite.[1]

Of these genera our limits do not permit us to give the characters at length. Of their British representatives the number is most imperfectly ascertained, and no department of our native zoology has been so greatly neglected. We need not painfully search the "dark unfathomed caves" for novelties, so long as the surface of our heaving ocean teems with varieties undescribed and unknown. Of such as are known, the student will find the fullest account in Dr Fleming's *History of British Animals;* and of several species not specified in that excellent work there are notices and figures in Loudon's *Magazine of Natural History*, more particularly in the ninth volume, where Mr Templeton describes the Irish species.

ORDER II.—ACALEPHES.[2]

After the example of Macleay, we restrict the application of this term to some families of Arachnodermata, which, by their fantastic forms, are estranged from the typical tribes, and exhibit in their organization such a variableness among themselves, and such a mixture of the elements of more than one class, that their true position among animals is rendered doubtful; and we are fain, in order to preserve distinctness and precision to our definitions of the various classes, to set them aside as anomalous, or annectant, or osculant groups, which, like corner-stones in a building, are adapted, by their very irregularity, to cement and gird the whole together. Most naturalists have believed them to bear the closest alliances with the Medusides, more particularly with the Cirrhogrades; but Blainville deems them to have superior claims to a connection with the Mollusca.[3] A common character can scarcely be assigned to the order. They are gelatinous, nomade, sometimes globular and radiated, more usually without any radiation, and deviating widely from familiar objects, so that we might compare them to the beautiful but misshapen orchideous and cryptogamous plants which blossom in the shades of the tropics, rather than to any animals which even the fancy of the herald-at-arms has yet pictured. Hence we shall distribute the little we have here to say of them under the two families which the order embraces.

The first family is named by Blainville Physogrades, an air-bladder being their principal organ of locomotion. Its general character is defined to be a regular symmetrical, bilateral, fleshy, contractile body, often greatly elongated, constructed with an air-bladder of greater or less size, which Blainville supposes, in the spirit of a transcendental anatomist, to be formed by a partial inflation of the intestinal canal, that has always a mouth and anus distinct from each other, and placed at the opposite extremities. The respiratory organs, according to the same author, reside in the lengthened irritable cirri attached to the body, and with which the ovaries are intermixed. The animals appear to have the power of secreting air, by which means the bladder can be filled more or less completely, and their buoyancy and position regulated according to their instincts. Whether the air is again absorbed when the floating Acalephes wish to descend, or whether it is ejected by compression from certain appropriate orifices, has been disputed. The latter is the common, and, as we believe, the correct opinion. A different opinion is however entertained by Dr Grant; for after a storm of three days endurance, he found many Velellæ cast on the shores of Cornwall, which should, on our hypothesis, have sunk to the bottom, and thus, in its stillness, have avoided the wreck which they suffered.[4] But a fact which concerns the Velellæ alone, cannot be legitimately applied to the Physales, since the discrepancy in their structures manifestly prohibits such an application. With relation to the Physales, Mr Peacock says, "on compression, air escapes from the sac by small orifices at each extremity."[5] Mr Baird, who had many opportunities of making examinations of them, says of the same animals, "They have the power of contracting and dilating their membranous (air) bag at pleasure, and no doubt, by trimming it to the wind, make it act the part of a sail to propel themselves through the water. 'They are very often to be met with at sea,' says Sir Hans Sloane; 'and seamen do affirm that they have very great skill in sailing, and managing their bladder or sail with judgment for this purpose, according to the different winds and courses.' Upon attentively examining the narrow or free extremity of the bladder, a small round aperture is perceptible, surrounded by a circular zone of fibres, of a beautiful red colour, like the muscular fibres of the iris of the eye. Out of this small hole, which is not larger than would be sufficient to admit the passage of a very fine bristle, *I squeezed the air out of the bladder.*"[6]

[3] *Man. d'Actinologie*, p. 112. This view has been adopted by Quoy and Gaymard, and by Lesson. *Ann. des Sc. Nat.* n. s v. p. 235–6.

[4] *Proc. Zool. Soc. Lond.* iii. pt. i. p. 14.

[5] *Mag. of Nat. Hist.* n. s. i. p. 598.

[6] *Mag. of Nat. Hist.* iv. p. 476. Knowing Mr Baird's accuracy, we are disposed to receive his statement as correct; but it is opposed by Mr George Bennett, who states that he could never discover the orifice in question, nor expel air from the bladder without a puncture being previously made; and, moreover, that the partial escape of air from the bladder has no influence on the creature's buoyancy. See *Proc. Zool. Soc. Lond.* for April 1837, p. 43.

The genera enumerated by Blainville as appertaining to the family are,

1. Physalus,
2. Physsophora,
3. Diphysa,
4. Rhizophysa,
5. Apolemia,
6. Stephanomia,
7. Protomedea,
8. Rhodophysa,
9. Cucubalus,
10. Cucullus,
11. Cymba,
12. Cuboides,
13. Enneagona,
14. Amphiroa,
15. Calpe,
16. Abyla,
17. Diphyes,
18. Pyramis,
19. Praia,
20. Tetragona,
21. Subculeolaria,
22. Galeolaria,
23. Rosacea,
24. Noctiluca,
25. Doliolum.

Of these the Physalus is the most celebrated. It is known to sailors as the *Portuguese man-of-war*, and almost every book of voyages into distant lands contains some account of its habits, mixed, as we may notice in the above extract from Sir Hans Sloane, with a little fable. One of the earliest descriptions of it is given by Clayton in his account of a voyage to Virginia, which we extract, because it is sufficiently descriptive, and gives the notions of the period regarding its nature. "In the sea I saw many little things which the seamen call *Carvels.* They are like a jelly, or starch that is made with a cast of blue in it. They swim like a small sheep's bladder above the water. Downwards there are long fibrous strings, some whereof I have found near half a yard long. This I take to be a sort of sea-plant, and the strings its roots growing in the sea, as duck-weed does in ponds. It may be reckoned among the potential cauteries; for when we were one day becalmed, getting some to make observations thereof, the sportful people rubb'd it on one another's hands and faces, and where it touch'd, it would make it look very red, and make it smart worse than a nettle."[1] Of the tentacula which hang from the lower edge there are two kinds; the longest being used by the Physalus for the capture of its prey, and capable of being coiled up within half an inch of the air-bladder, and then darted out with astonishing rapidity to the distance of twelve or eighteen feet, twining round and paralyzing, by means of an acrid secretion, any small fish within that distance. The food thus seized is rapidly conveyed to the *short* appendages or tubes, which are furnished with mouths for its reception.[2] The creature is not only vesicatory, but luminous in a high degree; and we may here remark, that these properties are probably common to every species of the family.

Of the other genera all are remarkable for singularity of form. We might single out as among the most curious, the *Rhizophysa*, from its likeness to a bulbous root, with long radicular fibres, and the *Physsophora*, which imitates a root partly bulbous and partly tuberous; the bulbs represented by the air-vesicles which are clustered above on a common stalk, and support the animal[3] in an upright position, while under them the stalk parts into many unequal tubers, whence depend the fibrilose radicles, which are the organs of respiration. The *Apolemia* and *Stephanomia*, if possible, surpass this eccentricity of form; they are living clusters of sea-grapes or currants, with tentacula of curious structure pullulating from amidst the berries.[4] The *Diphyes*, although less attractive, yet deserve notice from the view Cuvier takes of their organization. He believes that each animal, as it is usually taken, consists of two different individuals, one being emboxed in a cavity of the other; an arrangement which permits them to separate without destruction to individual life. The *Noctiluca* is pre-eminent for its luminosity. It is a minute gelatinous spherical body, with a depression on one side, whence protrudes a sort of contractile stalk or proboscis; and we strongly suspect it is the same with the Medusa scintillans of our shores, better or more amply described and delineated. Mons. Surivay, to whom we owe our fullest knowledge of the Noctiluca, mentions that it seemed to have disappeared entirely from its ordinary habitats in the Channel during the period of the prevalence of the cholera at Havre, which was in the months of May, June, and July 1834.[5] The fact is too remarkable not to be recorded, and seems to point to an atmospherical poison as the cause of that plague.

De Blainville gives to the second family the name of *Ciliogrades*,[6] because they move about in the ocean by means of certain rows of vibratile cilia which garnish the body. They are gelatinous, translucid, fragile, very irritable and contractile animals, of multiform aspects, but always evidently binary or bilateral, although there are not unfrequently some signs of a tendency to radiation in their structure. Thus the genuine Beroës are egg-shaped or globular, girded longitudinally with eight ciliated bands, equidistant or in pairs, so as to force a comparison between them and the Echinus with its ambulacral grooves.[7] The alimentary canal is usually described as traversing the body from pole to pole, with an orifice to each, the inferior and larger being the mouth, while the vent opens opposite in the centre of the apex. Near the middle of the body the canal is dilated into a stomachal cavity, at the sides of which the ovaries are usually to be distinguished by their vivid coloration;[8] and from the same cavity there run two or more canals, which tend towards the tentacula, on the lower surface, and carry water to them; for their elongation and various movements are dependent on the propulsion of water into them from behind, or its reflux back within the stomach.[9] The bands on which the cilia are placed run from the inferior or oral extremity, to the opposite one, always in straight lines; they are of firmer consistency than the rest of the body, and are apparently formed by a duplicature of the thin skin, so inserted as to leave a fine canal between their base and the surface. Through these canals there is probably a constant flow of water, and it has been suggested by Professor Grant that the play of the cilia may be maintained by this current, for muscular action for such a purpose seems to be inadequate.[10] Our knowledge of their generation is very imperfect. Eschscholtz has seen minute Beroës, which even then had a close resemblance to their adult parents, but they were destitute of the eight rows of natatory lamellæ. He could perceive in them only four opaque longitudinal bands, which were probably the rudiments of as many rows of lamellæ. These lamellæ then are developed not until after the body has assumed the figure characteristic of the species; and of the eight rows which these all possess, it appears that at first there are only four, between which the others are afterwards produced.

[3] "Mr Milne-Edwards believes that these (Physsophores) are not single animals, but the aggregation of a great number of individuals growing by buds, and living united together like the compound polypes." *Ann. and Mag. of Nat. Hist.* i. p. 156.

[4] The Stephanomiæ are, according to Lamarck, *compound* animals, consisting of a cluster of individuals which enjoy a common life and mutual communications through the medium of the central tube to which they hang. *Anim. sans Vert.* ii. p. 462.

[5] *Mag. of Zool. and Botany*, i. p. 492.

[6] The *Vibrastes* of Chamisso; *Beroides* of Lesson.

[7] The boatmen of Sheerness are familiar with the *Beroë pileus* "under the name of the spawn of the sea-egg (Echinus), which it somewhat resembles in its globular and ribbed form." Grant in *Trans. Zool. Soc.* i. p. 9.

[8] "I have generally observed that the lively hues presented by the Acalepha depend on the bright opaque colours of their reproductive gemmules, which are often red, sometimes yellow, or brown, or purple." Grant in *loc. cit.*

[9] This description has been lately pronounced by Mr Forbes and Mr Goodsir to be inaccurate. They believe the supposed anus to be imperforate, and a great portion of the supposed intestinal canal to belong to the circulating system.

[10] Grant *ut sup. cit.* p. 12. Dr Fleming observed in Beroë ovatus water moving in vessels along the middle of the bands to which the cilia are attached. The animals can change the direction of the currents in the vessels, and also the direction of the motions of the cilia.

The Ciliogrades abound in all seas, but many of them are rendered invisible to our dim vision by their pellucidity and small size. They move about with great alacrity, sometimes whirling on their own axis, or advancing forward obliquely, or rising to the surface and again quickly descending. As already mentioned, their principal organs of locomotion (and they are at the same time the organs of respiration) are the banded cilia, aided however by the contractility of the body itself, perhaps also by currents of water flowing through them, and in some genera (*Ocyroes*) by the undulatory movements of certain fin-like expansions peculiar to them. When they wish to repose, they poise themselves in mid water by the aid of their tentacula, or by ceasing the play of the cilia; but motion, constant motion, is their joy and occupation. Their vivacity, their extreme delicacy and fragility, the purity of the tints which colour their internal organs, and their varying iridescence reflected from the surface by the changes and motility of their cilia, have made them the objects of admiration to every one who has seen them. The Beroë ovum is, in the estimation of Otho Fabricius, the most beautiful of the class, but so frail as to be injured and broken by the gentlest handling; and when we remember that their life is probably as transitory as that of the Ephemera, it does indeed require from their admirers all the philosophy of the poet to bid him say, unrepining,

> Oh! mourn not, that in nature, transitory
> Are all her fairest and her loveliest things.

The family is coequal with the order Ctenophores of Eschscholtz, whose arrangement of the genera, though not the latest, is considered the most satisfactory. He divides the order into families and genera thus:

1° Callianirides, which have a small stomachal cavity and tentacula.
  A. Tentacula simple, furnished with delicate filaments.
    (*a*) Body extended laterally in the form of a ribbon. *Cestum.*
    (*b*) Body globular or ovoid. *Cydippe.*
  B. Tentacula ramified. *Callianira.*
2°. Mnemiides, which have a small stomachal cavity without tentacula.
  A. With straight prolongations near the mouth.
    * With rows of vibratile cilia on the body.
      (*a*) Surface of the body furnished with papillæ, without large lobes at the mouth. *Eucharis.*
      (*b*) Surface of the body even, with large lobes at the mouth. *Mnemia.*
    ** No rows of vibratile cilia on the body. *Calymna.*
  B. Without straight prolongations at the mouth. *Axiotima.*
3°. Beroïdes, which have a large central cavity in the place of the digestive cavity.
  A. The rows of vibratile cilia exposed.
    (*a*) Cilia shorter than the interspaces. *Beroë.*
    (*b*) Cilia one half longer than their interspaces. *Medeæ.*
  B. The rows of cilia in furrows, in which they can be hidden. *Pandora.*

Mr Edward Forbes has kindly furnished us with the following synopsis of the British Ciliograda.

I. Cydippe. Eschscholtz. Filamentary appendages.
  1. *C. pileus*, Linn.—Rows of cilia nineteen or twenty, on the summits of the lobes; filamentary appendages white. *Hab.* East coast of Scotland and England: Irish Sea: Isle of Man.
  2. *C. Flemingii*, Forbes.—(Beroë ovatus, *Flem.*) Rows of cilia thirty-six, on the summits of the lobes; filamentary appendages white. *Hab.* St Andrews Bay.
  3. *C. lagena*, Forbes.—Rows of cilia about twenty-five, placed in the furrows of the lobes; filaments white. *Hab.* North coast of Ireland.
  4. *C. pomiformis*, Patterson.—Rows of cilia about twenty; filaments rufous. *Hab.* Coast of Ireland and Firth of Forth. (Mr Patterson has given us a history of this species, written in a peculiarly interesting and pleasing style, in the *Trans. of the Royal Irish Academy*, v. xix., part 1st.)

Polypes.

Obs.—Mr Forbes and Mr Goodsir have made many observations on the cilia of this genus, which lead to important conclusions on the nature of these organs in general. They found, as Mr Garner had previously ascertained, cilia on the walls of the stomach and vessels, and a row of minute ones surrounding the mouth; but none was seen on the filamentary tentacula, or on the walls of the filamentary cavities. The cilia which are placed on the longitudinal ridges are linear-lanceolate, flat, and not hollow. They are not webbed together, and have no communication with the vessels which run beneath the ciliary ridges. Each row of cilia is mounted on a transverse base of a more solid texture, and less transparent than the rest of the body. The substance of this base consists of globules irregularly imbedded in a homogeneous substance. When one of the cilia of a Cydippe is cut off, it has of itself no power of motion; but if the smallest portion of the substance of its base remains attached, it moves with great vivacity. Hence the observers conclude that the ciliary motion is effected by the *undulatory movements of this peculiar tissue*; which explanation will also account for the rotatory appearance of the circles of cilia on certain animalcules. *Athenæum*, Sept. 26, 1840, p. 746.

II. Alcynöe, Rang. Tentacula round the mouth.
  1. *Al. rotunda*, Forbes and Goodsir.—Ovate, rounded, crystalline; tentacula rounded at their extremities; natatory lobes forming half the animal. *Hab.* Kirkwall Bay, Orkney.
  2. *Al. Smithii*, Forbes.—Elongate-pyriform, sub-compressed, crystalline; natatory lobes about a third of the length of the animal; tentacula acute lanceolate. *Hab.* Sea near Ailsa Craig.
  3. *Al.* [*Bolina*] *Hibernica*, Patterson.—Ovate, crystalline; tentacula acute; natatory lobes nearly one half the length of the animal. An Mnemia Norvegica, *Sars.* ? *Hab.* Irish coast, *Mr Patterson*, who has described it excellently in the work above quoted.
III. Beroe, Linn. Neither tentacula nor appendages.
  1. *B. cucumis*, Otho Fabricius. No spots on the external surface; internal dotted with red points; ciliaferous ridges red. *Hab.* Isle of May, in the Firth of Forth.
  2. *B. fulgens*, Macartney. *Hab.* Hearne Bay.

Obs. The "Eulimena quadrangularis" of Fleming appears to have been a ciliograde. The name Eulimena is pre-occupied for another genus of Medusa.

IV.—POLYPES.

The constituents of this class are in general animals of minute size, and of almost gelatinous consistency, characterized by having the oral aperture in the superior disc or extremity of the body encircled with a row, or sometimes with several rows, of tentacular filaments. The aperture always leads into a cavity appropriated to the digestion of the nutrient matter, but in all other particulars the Polypes differ so widely in their organization, that to give a view of it which shall have any distinctness or use, there is a necessity to separate the class into groups, founding their distinctions on that knowledge of their anatomy which has been recently obtained through the labours of Cuvier, Blainville, Savigny, Rapp, Grant, Thompson, Ehrenberg, Milne-Edwards, Dujardin, Farre, Lister, and others.

It is an axiom, that no class of animals stands isolated, but every one has its kindred claims on those around it, proving, not that each has been evoked from the pre-existent class by innate or external influences, but that the Creator has perhaps called his creatures into existence by a fiat worded in one spirit, and which matter has obeyed with one uniform intelligence. And thus it happens, that while Polypes have mostly felt the force of radiation in their development, they are not without their families that connect them with the unsymmetrical molluscans; and since it seems to us to be of importance that these relations should be remembered (for what study is more interesting to the zoologist than the mutual harmonies of two apparently remote classes?) we shall in the first instance divide the class into two sections, distinguished in a manner that brings this relationship into prominent view. The molluscan Polypes have both an oral and an anal aperture to the alimentary canal, and the tentacula that surround the former are filiform and ciliated; but the radiated Polypes have only one aperture to their digestive sac, serving by turns the purposes of a mouth and a vent, and the tentacula that guard it are not ciliated, but very contractile.

I.—MOLLUSCAN POLYPES.[1]

The molluscan Polype is always a very small, almost a microscopic animal, with an elongated, slender, subcylindrical body, which is bent upon itself like a syphon, so that the two extremities approximate each other. The mouth is a wide edentulous aperture, situated in the centre of the circle of tentacula, which rise from its rim, and constitute a funnel-shaped coronet of extreme delicacy. The number of filaments of which the coronet consists is very variable, but each of them forms a long slender filiform tube, clothed on one side with vibratile cilia, by whose active and well-regulated movements a current of water is incessantly driven along them in one determinate direction. These currents not only supply a succession of unbreathed water to the animal for the purpose of respiration, but they carry in their stream the animalcular prey that the polype feeds upon. Under the tentacular coronet the alimentary canal forms a kind of pouch analogous to the branchial sac of the ascidian mollusca, and, like it, plaited usually in a longitudinal direction. From this pouch or pharynx the gullet descends a short space previously to its dilatation into the stomach,—an organ usually of an oblong shape, with its wells studded with spots of a rich brown colour,—apparently hepatic follicles, that secrete a fluid which often tinges the whole organ, as well as its contents, of a similar hue. The intestine, on departing from the stomach, makes a sudden bend, to which is suspended a large short cæcal appendage; and afterwards the intestine proceeds upwards in a course parallel with the gullet to its termination, which is a little below the mouth, behind the pharynx, and on the side of the membranous sheath containing the tentacula.[2]

This kind of polype is never found isolated and naked. It dwells enclosed in a calcareous or horny cell, of which a great number is placed in juxtaposition, usually after a quincunx pattern; and the entire congeries forms sometimes a leprous crust, sometimes a stony branched coral, sometimes a fleshy unformed mass, and at other times a horny flexible sea-weed like polypidom, or one that more nearly resembles some fine capillary moss or shrubby lichen. The numerous tenantry of these aggregations are besides all connected together, so as to form what has been named a "compound animal;" every individual capable of self-support and of continuing its kind, yet so connected with the rest as necessarily to participate in every good and every evil that affects the community. The polypes are so connected with their cells that they cannot leave them, for indeed the cell and polype are merely parts of the same body. This, such as it has been described above, is enclosed in a thin membranous sac; and the cell is formed by a continuation of this tunic reflected over the inner layer, and hardened by the deposition in it of calcareous or albuminous matter to fit it to endure with impunity the contact and friction of the circumfluent waters, or to protect the soft viscera from accident and from the access of their enemies. Milne-Edwards compares the cell to the lopt finger of a glove, which has had its open truncate extremity ornamented with a thready fringe, capable of being withdrawn by an act of involution within the finger-stool. The point of junction between the retractile portion and that which is not so, constitutes, when the finger or polype is withdrawn, an opening usually called the mouth of the cell, which is very often overhung with a sort of moveable lip or valvular fold named the operculum. Two muscular bands are attached to the inner surface of this valve, and their office is to draw it down and shut close the cell when the tenant has retired for rest or from danger.

The polypidom, formed frequently of a congeries of many thousand cells, invariably begins with one only. This original or seminal cell has no sooner been completed (or even in many instances previously to its perfection) than another begins to shoot out from a fixed point of its parietes, the bud gradually enlarging and developing itself until the form and size of the primary one has been attained. This process can most easily be traced in the common sea-matts (Flustra) and Lepraliæ, where, round the margin of the crust, cells can at all seasons be observed in every stage of their evolution; one just budding, another half formed, and others again nearly complete. They never begin their original in the body of the polype, but always from the parietes, or from the connecting medium of the cells; and it is not until these have made considerable advances to maturity that the polype becomes distinguishable within them.

From this mode of increase there would seem to be no natural limits set to the magnitude and duration of the polypidom, except what arise from accident or exterior causes. The original polype and its immediate successors may grow old, languish, and die; but the solid cells remain in their connection as a root and fixture, while the newer races, which have sprung up towards the outskirts, continue their work, generation following generation in rapid and ever-multiplying successions. The polypidom in this respect resembles a tree in its growth: the trunk and main branches have stood years and centuries, but the increase has been made by annual shoots and renewals, and the last only know vigour and juvenescence. And as the form of the tree depends on the fashion of its ramifications, so that of the polypidom on the mode of evolution of its cells, for every part of the axis is not equally organized to produce buds, nor the same parts in all. Hence, if the primitive cell has only one point fitted for this generation, the polypidom will be built up in a catenated chain; if the cell has two points, two series of cells are formed, and in several the multiplication goes on in a regular arithmetical progression; but in others the cells are heaped together without apparent regularity, as in Alcyonella and Alcyonidium, where the softness of all the parts seems to allow of an irregular succession of buds. In this order, however, the general disposition of the cells is certainly after the quincunx, affording examples which the learned Sir Thomas Browne would have gladly adduced in proof that "Nature geometrizeth and observeth order in all things, and of the generality of this mystic figure."

The molluscan Polypes are all hermaphroditical and oviparous. The ova, which originate in the organized medium connecting the individuals together, are lodged and matured within the cell in some families; but in others their matrix is a little pearly globe that is placed over the mouths of the cells, and often constitutes the principal beauty of the specimen. When ripe for expulsion, the ova are of a vivid orange or yellow colour, of a roundish shape, and clothed with vibratile cilia, by means of which they swim about to and fro in the water like beings endowed with volition, and scatter themselves abroad.

The structure and form of the polypes seem to be very much alike throughout the entire class, so that it becomes necesssary to resort to the more varied polypidom for the basis of a method to arrange it into families and genera. Many such methods have been proposed, but in general so little are they in harmony with the structure of the animated tenants that they are of little value. Of the more recent ones none appears to us so good, as no one is so comprehensive, as that of the celebrated Ehrenberg, an outline of which is exhibited in the following table. We have only to remark, that the microscopic polythalamous shells which Ehrenberg arranges in the class for the first time, have been usually referred to the cephalopodous mollusca, where evidently they had no claim to be placed; and very lately Dujardin has contended, in opposition to Ehrenberg, that the animalcules inhabiting them are not of higher organization than the homogeneous and gelatinous Infusoria.[1]

Bryozoa.

Animalia asphycta, tubo cibario simplici, sacciformi aut tubuliformi, vera corporis articulatione nulla aut sensim numerosiore, corporis forma gemmis aut novis articulis accedentibus sensim aucta, hinc indefinita, nunquam sponte dividua, omnia et singula verisimiliter periodice ovipara, ideoque hermaphrodita.

Ordo I.—Polthalamia.

Libere vagantia et loricata.

Monosomatia.

Familia I. Miliolina.

Genera 2. ? Miliola, ? Gromia.

Familia II. Nodosarina.

Gen. 11. Glandulina, Mucronina, Nodosaria, Orthocerina, Dentalina, Lingulina, Frondicularia, Rimulina, Vaginulina, Planularia, Marginulina.

Familia III. Textularina.

Gen. 6. Bigenerina, ? Dimorphina, Textularia, Grammostomum (*Vulvularia*), Polymorphina, Virgulina.

Familia IV. Uvellina.

Gen. 11. Guttulina (et *Globulina*), Uvigerina, Bulimina, Valvulina, Rosalina, Clavulina, Globigerina, Pyrulina, Sphæroidina.

Familia V. Rotalina.

Gen. 22. Operculina, Soldania, Planorbulina, Rotalia, Trochulina, ? Spirulina, Calcarina, Pleurotrema, Planulina, Discorbis, Omphalophacus, ? Gyroidina, Truncatulina, Lenticulina, Nonionina, Cristellaria, Siderolina, Dendritina, Robulina, Anomalina, Saracenaria, Cassidulina.

Familia VI. Plicatilia.

Gen. 6. Biloculina, Spiroloculina, Triloculina, Articulina, Quinqueloculina, Adelosina.

Polysomatia.

Familia VII. Asterodiscina.

Gen. 5. Asterodiscus, Lunulites, Orbitulites, Cupularia, Flustrella.

Familia VIII. Soritina.

Gen. 2. Sorites, Amphisorus.

Familia IX. Frumentarina.

Gen. 3. ? Dactylopora, ? Ovulites, ? Polytripe.

Familia X. Helicosorina.

Gen. 5. Peneroplis, Pavonina, Vertebralina, Orbiculina, ? Heterostegina.

Familia XI. Helicotrochina.

Gen. 3. Polystomella, ? Amphistegina, ? Geoponus.

Familia XII. Alveolinea.

Gen. 2. Melonia, Alveolina.

Familia XIII. Fabularina.

Gen. 2. Fabularia, Coscinospira.

Ordo II.—Gymnocoræ.

Libere vagantes, nudæ.

Familia I. Cristatellina.

Gen. 2. Cristatella, Zoobotryon.

Ordo III.—Thallopodia.

Stolonibus thallove membranaceo affixa, incrustantia nec adnata, sed loricata.

Familia I. Halcyonellea.

Gen. 8. Halcyonella, Vesicularia, Bowerbankia, Farrella (= *Lagenella*), Valkeria, Stephanidium, n. G. Dynamene, Halodactylus (= *Alcyonidium*).

Familia II. Cornularina.

Gen. 1. ? Cornularia.

Familia III. Escharina.

Gen. 5. Eschara, Melicertina (= *Melicerita*), Crisia, Acamarchis, Notamia.

Familia IV. Celleporina.

Gen. 5. Cellepora, Flustra, Membranipora, Briolophus, n. G. Apsendesia.

Familia V. Auloporina.

Gen. 1. Tubulipora.

Ordo IV.—Scleropodia.

Stolonibus destituta, excreto fulcro axique anorganicis firmiter affixa eisque fruticulosa.

Familia I. Myrioporina.

Gen. 9. Hornera, Idmonea, Retipora, Distichopora, Myriopora, Tilesia, Cricopora, Ceriopora, Spiropora.

Familia II. ? Antipathina.

Gen. 1. Antipathes.

This extensive class contains few or perhaps no species that contribute directly to the use of man, or interest him by their applications to the arts on which he prides himself. Their instincts and habits are obscure; and although the beauty and variety of their polypidoms is singularly great, the pattern is on too minute a scale to have ever engaged vulgar attention. Their influence on the earth's surface is however not inferior to that of any class of animals whatever. Large formations of limestone, of chalk and chalk-marl, and extensive banks of sand, have been the result of their active life, and prodigious multiplications, continued over untold ages. "Many, and probably all, white-chalk rocks," says Ehrenberg, "are the produce of microscopic coral-animalcules, which are mostly quite invisible to the naked eye, possessing calcareous shells of $\frac{1}{24}$ to $\frac{1}{288}$ line in magnitude, and of which much more than one million are well preserved in each cubic inch; that is, much more than ten millions in one pound of chalk."[2]

The Radiated Polypes, or Anthozoa of Ehrenberg, present us with a greater diversity of structures than the molluscans. In all, the body is perforated superiorly with the larger circular opening into the digestive cavity, and surmounted with a coronet of tentacula; but the structure of the stomach, and the disposition of the tentacula, vary so much, that if our classification would follow and reflect a representation of the principal modifications of this variety, we are constrained to subdivide the class into three sections as follows:

I. Helianthoida. *Polypes* single or aggregate, free or permanently attached, fleshy, naked, or encrusted with a calcareous *polypidom*, the upper surface of which is crossed with radiating lamellæ; mouth encircled with tubulous tentacula; stomach membranous, plaited; intestine 0, anus 0; oviparous, the ovaries internal.

II. Asteroida. *Polypes* compound, the mouth encircled with eight fringed tentacula; stomach membranous, with dependent vasculiform appendages; intestine 0, anus 0; reproductive gemmules produced interiorly. *Polype-mass* variable in form, free or permanently attached, carnose, generally strengthened with a horny or calcareous *axis*, enveloped with the gelatinous or creto-gelatinous crust in which the polype-cells are immersed, and which open on the surface in a starred fashion with eight rays.

III. Hydroida. *Polypes* compound, rarely single and naked, the mouth encircled with roughish filiform tentacula; stomach without proper parietes; intestine 0, anus 0; reproductive gemmules pullulating from the body, and naked, or contained in external vesicles. *Polypidoms* horny, fistular, more or less phytoidal, fixed, external.

I.—HELIANTHOIDA.[1]

The typical representatives of this order are the *Actiniæ* or sea-anemonies. which abound on every European shore between tide-marks, rivalling in beauty and vividness of colouring their floral namesakes. It is now well ascertained that the animals of the madrepores, sea-mushrooms, and brainstones of tropical seas, differ from the Actiniæ no otherwise in essence than in their power of excreting, from the inferior portion of the body, a large quantity of calcareous matter, the deposition of which under and around the body, and in the tissue of the folds formed by the tunics of the abdominal cavity, constitutes the cell or polypidom, into whose hollows the tenant can partially or wholly retire. "The stony substances so formed are called *corals*, and their mode of formation causes them exactly to represent the animal which secretes them: the upper surface is always furnished with radiating plates, the remains of the calcareous particles which were deposited in the longitudinal folds of the stomach, before referred to; and as these plates do not usually reach to the centre, there is almost always a vacant space in the middle between them." The cells are either single and cupped, or they are branched like a tree, or they are aggregated together so as to resemble a cauliflower, or even to imitate the human brains; all these variations resulting from the manner in which the animal emits from the whole surface, or from a particular part of the sides of the body, the bud by which the new individuals of the general mass or society are produced.

The Helianthoida are all oviparous, the ova being produced in appropriate ovaries situated between the compartments formed by the septa that radiate from the outer parietes of the stomach to the skin. The ova are contractile and motive, being carried about from the action of the cilia that clothe the surface. "Under the microscope they prove of diversified form, many resembling flattened peas, some elongated or exhibiting irregular prominences, some almost spherical, and some which cannot be referred to any particular figure." After moving about for several days, during which their forms suffer some slight change, they insensibly relax in their motility, the cilia disappear, and having become stationary, each ovum rapidly runs through the stages of development that lead it up to the similitude of its parent.

The productiveness of the species and the rapidity of their growth are very great. The calcareous species often form enormous masses of coral, of the size of which we cannot judge by the specimens usually shown in collections, which are small individuals taken in the sheltered places among the rocks, where they are not exposed to the action of the waves, and collected before they have reached their proper magnitude. "The form of the masses appears to be greatly influenced by the positions in which they have grown, and the size of the individuals greatly depends on the quantity of nourishment they are able to procure. This is proved by the fact, that if all the individuals of the same mass are equally exposed, they are of an equal size, but if the surface of the coral is waved, as in the *Explanaria*, the individuals on the convex part of the mass, which could procure the most food, are large, while those in the concave or sunken parts are small."—*J. E. Gray.*

It is to the polypes of this order that the origin of the coral islands in the Pacific and other tropical seas are principally ascribed. The quickness of their growth, and the depths from which they rise, have been undoubtedly exaggerated; yet this, with every deduction, is so great that the coral-bearing Helianthoida are justly reckoned the principal operators in the mutations of the bed of every tropical sea, as they were in the seas of the primeval world. They roughen the bottom and fill up hollows in every shallow sea; they occupy the tops of reefs in deeper ones, and bar up the entrance to harbours and lagoons; they cap submarine mountains, and bring them to the surface; and they lay up everywhere the materials for the formation of future quarries of limestone.

The families and genera into which the Helianthoida have been distributed are as follows:

Fam. I. *Actiniadæ.*—Actinia; Anthea; Adamsia; Iluanthos; Metridium; Megalactis; Actinodendron; Epicladia; Heterodactyla; Lucernaria.

Fam. II. *Zoanthidæ.*—Isaura; Hughea; Zoanthus; Mammillifera; Corticifera.

Fam. III. *Madreporidæ.*—Fungia; Turbinolia; Diplocterium; Cyclolithes; Desmophyllum; Cyathina; Caryophyllia; Manicina; Oculina; Stephanocora; Cladocora; Columnaria; Strombodes; Cyathophyllum; Pterorrhiza; Anthophyllum; Stylina; Favia; Astræa; Dictyophyllia; Favosites; Monticularia; Meandra; Dendrogyra; Turbinaria; Explanaria; Merulina; Pavonia; Agaricia; Polyastra; Haliglossa; Polyphyllia.

Fam. IV. *Poritidæ.*—Madrepora; Porites; Alloporina.

Fam. V. *Pœcilloporidæ.*—Seriatopora; Anthopora; Pœcillopora; Heliopora.

Fam. VI. *Milleporidæ.*—Millepora.

Fam. VII. *Distichoporidæ.*—Distichopora.[2]

II.—ASTEROIDA.[3]

The name of this order is derived from the starred marks that stud the surface when the polypes have contracted and hid themselves under the skin of the common mass or polypidom. These marks are produced by the incisures whence the tentacula are evolved; and hence the number of rays in each mark is mostly eight, but sometimes only six in number, corresponding with the number of tentacula. These organs are, in this order, comparatively short, thick, and fringed or pectinated on the margins, and they radiate from a flat disc, in the centre of which the mouth is situated. This aperture is always circular, and leads by a gullet into a long cylindrical stomach, which is as it were suspended in a thin membranous sac or vesicle, and kept in its central position by eight or six septa or ligaments stretched between it and the vesicle, dividing the intermediate space into as many distinct compartments. From the inferior extremity of the stomach there hang eight or six twisted, intestine-like, but probably biliary, appendages, into a wide cavity, that communicates freely with the fleshy parenchyma by which the polypes are connected together, for the Asteroida are all compound Zoophytes; that is, each species is a collection of numerous individuals participating in a common life, while each individual at the same time enjoys an independent vitality for every part of its body. The connection is effected partly through the medium of the skin, which is formed by the confluence of the outer thickened tunic of the polypes, and partly by aquiferous ducts that depart from the infra-abdominal cavity just mentioned, and permeate the entire mass in every direction.

The forms of the polypiferous masses are very various. Some are fleshy amorphous productions, covered with a coriaceous skin loaded with variously-shaped calcareous grains or crystals; others resemble a quill, and are called Sea-pens; others are like a rush or rod; while many, like the Gorgonia and Coral, are eminently imitative of marine vegetations. The internal part of the amorphous species is

[3] Synonymes: Zoophytaria or Ctenocera of Blainville; Alcyoniens, M. Edwards.

Polype.

fibro-gelatinous; "but when the axis assumes an erect or a branched tree-like form, the animals excrete in the centre of their body a more or less rigid support, which has been called their *axis*, and which has sometimes, though erroneously (from its being commonly seen in collections without the remains of the investing animal), been considered the entire coral. This axis is thickened by depositions of fresh layers of horny matter on its surface as the mass increases in size and requires more support, the increase of the thickness and length of the axis being always simultaneous with the growth of the mass."—(*J. E. Gray.*) In some genera the axis is bony, in a greater number it is of a horny nature, and very compact, in a few it is formed by the aggregation of siliceous needle-shaped spicula, and in others it is calcareous and stony; of which we have a familiar example in the red and black coral of the Zoophyte that furnishes the coral of commerce, so highly valued for ornamental purposes. In the genus *Isis*, "the axis has been considered as jointed, because the stony and the horny parts easily separate from each other when the mass of the animal has been removed and the axis is dried; but a larger and larger quantity of stony matter is gradually deposited as the mass increases in size, and in the large masses the axis of the lower part is almost entirely stony, like the axis of *Corallium*."—(*J. E. Gray.*)

The Helianthoida are all oviparous, and it has been recently affirmed that the sexes are distinct and separate. Dr Erdl of Munich says that he found in *Veretillum* only female individuals in one polypary, and in another only males; and he has convinced himself of a similar distinction existing in the genus *Alcyonium* or *Lobularia*. Plate DVI. fig. 9.

According to J. E. Gray, this order arranges itself under the following families and genera:

Fam. I. *Cornularidæ.*—Cornularia.

Fam. II. *Clavulariadæ.*—Actinantha; Clavularia; Telesto.

Fam. III. *Tubiporidæ.*—Tubipora.

Fam. IV. *Coralliadæ.*—Corallium, Plate DVI. fig. 3; Isis; Mopsea; Melitœa; Prymnoa; Muricea; Scirpearia; Eunicea; Plexaura; Gorgonia; Pterogorgia.

Fam. V. *Antipathidæ.*—Antipathes; Leiopathes.

Fam. VI. *Briareidæ.*—Briareum.

Fam. VII. *Lobulariadæ.*—Lobularia; Ammothæa; Anthelia; Sympodium; Rhizoxenia.

Fam. VIII. *Zeniadæ.*—Zenia; Nephthya; Nidalia.

Fam. IX. *Hyalonemidæ.*—Hyalonema.

Fam. X. *Pennatulidæ.*—Pennatula, Plate DVI. fig. 8; Virgularia; Renilla, Plate DVI. fig. 11; Pavonaria; Veretillum.

Fam. XI. *Umbellariadæ.*—Umbellaria.

III.—HYDROIDA.[1]

The Hydra, or fresh-water Polypus (Plate DVI. fig. 10 and 14), of which more has been written than of any other Zoophyte, is the type of this order, very remarkable for the extreme simplicity of organization of its members, and for their wonderful powers of redintegration and reproduction. The polype, considered independently of its polypidom, possesses no defined organs whatever; but when highly magnified, the whole body is seen to consist of a granular substance, the granules being loosely connected by a semi-fluid albuminous matter. On the upper pole of this gelatinous and very contractile body there is an aperture encircled with a variable number of tentacula, roughened with nodules, and extremely extensible, so that the creature can spread and stretch them far and wide in search of prey, which consists of very active crustaceous animalcules and small worms. These are no sooner seized upon than they appear to be paralysed by some poisonous secretion of the polype, for their struggles and resistance are stopt as it were by magic, and they are carried unresisting to the mouth, and forced into the central digestive sac.

Sponges.

The Hydroida are reproduced by gemmules or buds, which are developed from the common substance of the body. In the Hydra they spring from no particular part, but in other genera they have a determinate origin, and in many others they are contained, like ova, in ovarian capsules, whence they are not discharged until ripe for evolution. But perhaps the most remarkable feature in the history of these Zoophytes, is their power of being multiplied by mechanical division. If a snip be made with a fine pair of scissors in the side of a Hydra, not only does the wound soon heal, but a young polype sprouts from the wounded part; if it be cut into two portions by a transverse incision, each soon developes the wanting parts of its structure; if longitudinally divided, both portions soon become complete animals; if it even be cut into several parts, every one of them will rapidly assume the form and functions of the original. The inversion of its body, by turning it inside out, does not destroy it; on the contrary, the exterior surface assumes the office of a stomachical cavity, and that which was originally internal will give birth to buds, and take upon itself all the properties of the skin. See R. Jones's *Outline of the Animal Kingdom*, p. 26.

The Hydra is locomotive and naked, but the majority of its order are permanently affixed to their sites, and are invested with a horny sheath or polypidom, which in many instances excels all other zoophytical productions in the delicacy and gracefulness of its form. These polypidoms are converfoid and more or less divided, the ramifications being divided in a variety of elegant plant-like forms. The stem and branches are alike in texture, slender, fistular, and almost always jointed at short and regular intervals, the joint being a mere break in the continuity of the sheath, without any character of a proper hinge, and evidently formed by regular periodical interruptions in the growth of the polypidoms. Along their sides, or at the extremities, we find the denticles or cup-like cells, within which the polypes are contained, arranged in a determinate order, and either sessile or elevated on a stalk. Plate DVI. fig. 12. Though of the same substance, the cell is something more than a simple expansion of the stem or branch; for near its base there is a distinct partition or diaphragm, on which the body of the polype rests, with a plain or tubulous perforation in the centre, through which the connection between the individual polype and the common medullary pulp is retained.

According to Mr J. E. Gray, this order embraces five families, viz.

Fam. I. *Hydraidæ.*—Hydra. Plate DVI. fig. 10 and 14.

Fam. II. *Tubulariadæ.*—Tubularia; Eudendrium; Corymorpha.

Fam. III. *Corynaidæ.*—Coryne; Syncoryna.

Fam. IV. *Sertulariadæ.*—Thoa; Sertularia; Dynamena; Thuiaria; Pasythea; Epistomea; Lirizoa; Plumularia; Antennularia; Cymodoce; Salacia; Idia.

Fam. V. *Campanulariadæ.*—Laomedea; Campanularia; Peripyxis.

V.—SPONGES.[2]

The Sponges differ so much from all other Zoophytes, that De Blainville has constituted with them a separate

---

[1] Synonymes: Sertulariens, M. Edwards: Polypiaria, J. E. Gray.

[2] Synonymes: Spongiæ; Spongiadæ; Spongiaires; Porifera; Amorphozoa.

Sponges.

class, under the denomination of *Amorphozoa*, to mark that want of a definite and constant form in their species for which they are remarkable in the animal kingdom. Their general appearance and structure must be familiar to every one. They are soft, elastic, porous or cellular bodies, of a uniform structure in every part, without any organs or vessels, and capable of absorbing large quantities of liquid, which they again yield up on pressure, without injury to their textures. They are quite insensible to every sort of irritation, and can contract neither the body as a whole, nor any portion of it; nor can they remove in any way from the site on which they have grown.

In a recent state the sponge is filled with a colourless animal jelly, the quantity of which varies much in different species. This jelly is apparently homogeneous; but, with the assistance of the microscope, it has been discovered to be full of numerous transparent spherical granules. It is diffused through every part of the sponge, filling the intercellular spaces, and it lines also the canals which permeate the mass, and often covers the surface with a slimy coat.

The sponges used in domestic economy are composed of a horny fibre, netted together so as to form small irregular meshes, with larger canals and holes interspersed. The fibre is solid and transparent, generally smooth, but sometimes closely invested with a fine branched vascular tissue. These sponges are soft, compressible, and eminently bibulous; but there is a gradual passage from them into others of a more rigid and compact texture; and on examining into the cause of this change, we find that the fibre has become loaded with crystalline needle-shaped spicula, which, chemical tests assure us, are formed of pure silex or flint. There are many sponges in which these spicula predominate so far that the horny matter has become of secondary importance; and such sponges, after being dried, resemble crumbs of bread, and are easily rubbed down into a powder merely by friction between the fingers. Mr Bowerbank has shewn that the transition from the fibro-horny to these siliceous sponges is insensibly made, and that many species which were believed to be purely fibrous, contain in fact numerous minute imbedded spicula.[1]

There is another class of sponges, rather of a felted than reticular structure, and containing a very scanty proportion of organic fluid. They are usually of a grayish-white colour, and are loaded with spicula, but the spicula are composed of carbonate of lime. These spicula are more variable both in form and size than the siliceous kinds; for in the same sponge we often find some which are needle-shaped, others that are club-shaped, and others that are formed of three or four divergent prongs. There has not been discovered any sponge in which the calcareous and siliceous spicula naturally co-exist; but some species of a compact fleshy texture have been described, in which, while the central parts are crammed with spicula of flint, the surface is covered with a layer of calcareous earth.[2]

In all sponges the surface is porous, and of a finer and closer texture than the interior, which is also permeated with some irregular sinuous canals, that open on the surface in the form of circular orifices, which have been called their *oscula*, but which are properly their vents. When living and in health, the sponge is continually imbibing by the pores the water which surrounds it. This water, penetrating to every part, fills the cells and distends the body equally; it is then forced into the canals, and driven, in an agitated current, from the body, through the oscula. By this circulation the air and food of the sponge is supplied, and its effete excretions removed; but by what agency it is originated and kept up, is not positively ascertained. Dr Grant thinks it probable that minute vibratile cilia planted in the canals and pores are the moving power; while Dutrochet ascribes the phenomena to that law of *endosmose* which he has discovered to regulate the transmission of liquids of unequal densities through all organic membranes.

Lithophytes.

Sponges are propagated by gemmules, which originate in the organic mucus, and are carried out of the body by the effluent currents just described. In some sponges these gemmules are ciliated and locomotive when mature; but it seems probable that the majority of the species produce only unciliated gelatinous grains, which are nevertheless endowed with a very active motility, like the ultimate particles of even inorganic matter.

With one or two exceptions, sponges are natives of the sea, ranging from tide-marks to a very considerable depth. They are scarce and small in cold latitudes, and gradually increase in size and numbers as we trace their course towards the tropics, but perhaps they abound most of all in the genial seas of the Australasian islands. The sponges of commerce are chiefly procured from the Mediterranean, and from the Bahama islands in the West Indies.

The classification of sponges is in a state of the utmost uncertainty, and most of the genera rest on very insufficient characters. The names of such as have been proposed are as follows:

Alcyoncellum.
Achilleum.
Cæloptycium.
Choanites.
Cnemidium.
Chenendopora.
Grantia.
Hallirhoa.
Hippalimus.
Halichondria.
Geodia.
Lymnorea.
Manon.
Myrmecium.
Siphonia.
Scyphia.
Spongia.
Tethia.
Tragos.
Ventriculites.[3]

VI.—LITHOPHYTES.[4]

The Lithophytes, in the restricted sense in which we use the term, are plant-like marine organized bodies, which adhere to other substances by a crustaceous base, and are composed of an internal fibrous axis encrusted over with a chalky porous bark, either continuous, or divided by septa into numerous equal articulations. From the time of Ellis, who was a strenuous advocate of their animality, they have been always described as members of the animal kingdom; but the observations of Blainville and Schweigger leave no doubt of their being truly vegetables, differing little from many algæ.

There are two families of lithophytes. In the first the calcareous crust is rather thick, compact or minutely porous, and jointed. The family corresponds exactly with the genus *Corallina* of Linnæus, subdivided by Lamarck and Lamouroux into the following genera: Cymopolia, Corallina, Jania, Flabellaria, Amphizoa, Penicillus, Galaxaura, Acetabulum, and Polyphysa. Many of the species are very pretty, and the Acetabulum is a parasol in miniature. Plate DVI. fig. 13. One species (*Corallina officinalis*) has been much celebrated as a powerful vermifuge.

The second family, from being more decidedly vegetable in its aspect, is named by Blainville *Fucoideæ*. In it the cretaceous crust which covers the stem and branches is very thin and continuous, and it offers to observation no trace of pores. The organic substance is also more gelatinous, and consequently approaches nearer to that of the true sea-weeds. The genera are, Udotea, Dichotomaria, Liagora, and Neomeris.

(D. M.)

ZOROASTER, or ZERDUSHT, a celebrated ancient philosopher, said to have been the reformer or the founder of the religion of the Magi. It is wholly uncertain to how many eminent men the name of Zoroaster belonged. Some have maintained that there was but one Zoroaster, and that he was a Persian; others have said that there were six eminent founders of philosophy of this name. Ham the son of Noah, Moses, Osiris, Mithras, and others, both gods and men, have by different writers been asserted to have been the same with Zoroaster. Many different opinions have also been advanced concerning the time when he flourished. Aristotle and Pliny fix the date at so remote a period as 6000 years before the death of Plato. According to Dionysius Laertius, he flourished 600 years before the Trojan war; according to Suidas, 500. If, in the midst of so much uncertainty, any thing can be advanced with the appearance of probability, it seems to be this, that there was a Zoroaster, a Perso-Median, who flourished about the time of Darius Hystaspes; and that besides him there was another Zoroaster, who lived at a much more remote period among the Babylonians, and taught them astronomy. The Greek and Arabian writers are agreed concerning the existence of the Persian Zoroaster; and the ancients unanimously ascribe to a philosopher whom they call Zoroaster, the origin of the Chaldean astronomy, which is certainly of much earlier date than the time of Hystaspes. It seems therefore necessary to suppose a Chaldean Zoroaster distinct from the Persian. Concerning this Zoroaster however nothing more is known than that he flourished towards the beginning of the Babylonish empire, and was the father of the Chaldean astrology and magic. All the writings that have been ascribed to Zoroaster are unquestionably spurious.

ZOSIMUS, a historian of Constantinople, who has had various editors, is supposed to have written in the fifth century. He is described as "comes et exadvocatus fisci;" and from his own work it is evident that he was not a Christian. He wrote the history of the Roman empire from the reign of Augustus to the year 410. The first book contains brief notices of the earlier emperors, ending with Diocletian; but in the other five books his details are more ample. A Latin version of this history was published by Leunclavius in 1576; and in 1581 H. Stephanus added the Greek text of the first two books to his edition of Herodian. All the six books were published by Sylburgius in the third volume of his "Romanæ Historiæ Scriptores Græci Minores." Francof. 1590, fol. This was followed by other editions, of which the best is that of Reitemeier, Lipsiæ, 1784, 8vo; Bonnæ, 1837, 8vo. The latter impression, forming a volume of Niebuhr's "Corpus Scriptorum Historiæ Byzantinæ," was superintended by Bekker, who has corrected the errors of the former edition, and has omitted such critical notes as he did not approve. In both these impressions, some annotations of Heyne are added to those of Reitemeier.

ZUG, a canton of Switzerland, the smallest of the whole confederacy. It is bounded on the north by Zürich, on the east and south-east by Schwytz, on the south-west by Lucerne, and on the west by Aargau. It is only 110 square miles in extent; and is divided into two parts, the inner and the outer amt or bailiwick. It contains 1876 dwellings, with 14,710 inhabitants. They are all of the German race, and speak that language. The religion is that of the Romish church, and the canton contains nine parish churches, with three monasteries, all under the bishop of Constance. The constitution is a pure democracy. All the males who have completed the age of nineteen must become soldiers, and must be regimented in the militia. An assembly of the whole inhabitants is held on the first Sunday in May, when the several officers are chosen for the year. The chief, called the Landamann, is elected for two years, and from the two bailiwicks alternately. The officers of the militia are nominated for life. The council consists of thirty-four members, and in ordinary times assembles three times in the year, and at such other periods as the chief may deem it necessary; but a committee of that body is permanent, and superintends the police, and forms a court of appeal from the ordinary tribunals. There are inferior authorities in each of the two bailiwicks, who rule in local affairs. The taxes are collected on liquids consumed, whether wine, beer, or spirits; besides which there are stamp-taxes, and payments for licenses to carry on trade; but the whole burdens are very light. The contribution of the canton to the general confederacy is 1250 francs, and the contingent of men 250.

The face of the country is alpine, but the highest mountain, the Ruffi, does not exceed 4830 feet. The other mountains, as the Rossberg, the Zugerberg, the Morgarten, and the Dreilanderstein, are lower. The river Reuss is the principal stream, which runs to the lake of Zug, and receives the smaller brooks. It forms the boundary with the canton of Aargau. The lake of Zug, one of peculiar beauty, is about nine miles in length and two and a half in breadth. The road by its side presents points of view and striking objects which charm the eye, and leave a lasting impression on the mind of the traveller. This lake is dangerous to navigate with a strong southerly wind, on account of the sudden violent gusts. It has however some trade on it, and is abundantly stocked with fish of various kinds. The lake of Eger, and that of Fenster, have their peculiar beauties, and, like that of Zug, abound in fish. The climate is that of the Alps, but rather milder than in some other parts. The soil is good, and yields corn and wine, much fruit, especially plums, and great quantities of walnuts and chestnuts. There are no manufactures except two paper-mills. The trade consists in the export of butter, cheese, cattle, wool, hides, dried fruits, and chestnuts. These are sufficient to pay for the few foreign necessaries and luxuries that are wanted. The chief profit is however derived from the very numerous foreigners who visit the country in the summer months, and who find good accommodations, but at no very cheap rate.

The capital of this canton likewise bears the name of Zug. It stands on the lake at the foot of a mountain. It is fortified, contains two churches, a Capuchin monastery, a hospital, a council-house, a workhouse, and 2800 inhabitants. It is a poor place, except at the time of the annual fair, which continues fourteen days, when there is an appearance of activity.

ZUINGLIUS, Ulricus, or *Ulrich Zwingli*, an able and zealous reformer, who laid the foundation of a separation from Rome in Switzerland, at the time when Luther was similarly employed in Saxony, was born on the first of January 1504, at Wildehausen in Tockenburg, a distinct republic in alliance with the Swiss confederation. He was sent to school at Basel, and afterwards at Berne, where he learned the Greek and Hebrew languages. He studied philosophy at Vienna, and divinity at Basel, where he took the degree of A. M. in 1506. While he officiated as preacher at Zürich, a Franciscan sent by Leo X. came to publish indulgences there; against which Zuinglius, after the example of Luther, declaimed powerfully. In the course of this opposition he started a new doctrine, which he called *Evangelical Truth;* and from the beginning of 1519 to 1523, he preached not only against indulgences, but against other articles of the Romish church. But though Zuinglius made no less progress than Luther, he conducted himself with more moderation; and wishing to have the concurrence of the civil powers, procured two assemblies to be called at Zürich. By the first, he was authorized to proceed as he had begun; and by the second, the outward worship and ceremonies of the church of Rome were abolished. During these transactions, Zuinglius published several books in defence of his doctrines; but treating of the eucharist, and prescribing a form of celebrating the Lord's Supper different from Luther, he was involved in violent disputes with the rest of his reforming brethren. Respecting the divine decrees, the opinion of Zuinglius and his followers differed very little from that of the Pelagians; and instead of declaring, with Calvin, that the church is a separate independent body, vested with the right of legislation for itself, Zuinglius ascribed to the civil magistrate an absolute and unbounded power in religious matters, allowing at the same time a certain subordination among the ministers of the church. This was abundantly agreeable to the magistrates of Zürich; but the rest of the Swiss cantons disallowing of their proceedings, the opposite parties had recourse to arms; and Zuinglius, who began as a preacher, died as a soldier, in 1531. His works have been published in four volumes folio.

ZULLICHAU, a city of Prussia, the capital of the circle of the same name in the government of Frankfort on the Oder, and the province of Brandenburg. It stands on a fertile plain, is surrounded with walls and ditches, and contains 760 houses, with 5900 industrious inhabitants, who are employed in making fine cloths, linens, hats, and hosiery, and in breweries and distilleries. It is the place where, of late years, many large and cheap editions of the most popular books in the English language have been printed very correctly; and it furnishes Germany with the writings of Scott, Byron, and others, at a price greatly inferior to that at which they can be imported, and thus contributes to extend the knowledge of our language and literature.

ZÜRICH, a canton of Switzerland, one of the most ancient of the confederation. It is bounded on one side by the dominions of the grand duke of Baden, and on all other points by the Swiss cantons of Schafhausen, Thurgau, St Gall, Schwytz, Zug, and Aargau. The whole extent of the canton is about 640 square miles, including the lakes. The population, by a census taken in the year 1837, was found to be 231,576 individuals, all of whom, except 2000 Catholics, belonged to the Protestant reformed church.

The canton is purely of German origin, using only that language, but with a strong patois among the country people. It contains six cities (so denominated from being or having been fortified), eight market-towns, 149 communes, and 467 villages, with 26,400 houses. The education of the people is carefully conducted. Besides a university in the capital, and several private institutions, there are no less than 385 public schools, in which more than 55,000 children are instructed in the lower branches of learning. The contingent of the canton towards the general defence of the confederation is fixed at 3700 men, and the annual payment of 74,000 francs. This canton is one of the governing departments, and is therefore, alternately with Berne and Lucerne, the residence of the diplomatic body, and of the persons engaged in the official business of the confederation. The surface of the canton may be properly described as an undulating succession of plains and hills of no great elevation, except two ranges, whose highest peaks are about 2000 feet above the level of the lakes, or about 3500 feet above the level of the sea. With the exception of those peaks, the land is fertile and well cultivated; producing corn, wine, fruits, and an abundant store of butter and cheese for the support of its own dense population. The towns and villages contain a most industrious population, chiefly employed in the manufacture of silk and cotton goods of a fine and elegant texture, which are formidable rivals of the English and French fabrics at the fairs of Frankfort and Leipzig, and in the cities of Germany. The rapid streams afford a power by which some very extensive cotton and silk mills are turned.

The most prominent feature in the face of the country is the lake of the same name as the canton. It forms a kind of crescent from east to west. It is about twenty-nine miles in length, and in breadth varies from three to four miles. It is chiefly supplied with water from the river Linth, into which descend the melted snows of the glaciers of Taede and Kistenberg. Though its depth in many parts is 600 feet, yet, owing to shoals in other parts, it is only navigable by vessels of a light draught of water, or by steamers, with which, within the last three years, it has, like the other lakes of Switzerland, been abundantly furnished. The lake in the hottest months is raised from ten to fifteen feet by the more rapid melting of the ice on the glaciers. The lake of Zürich is next to that of Geneva in extent; and, though destitute of the grandeur of scenery of that and of the Wallenstadt and Lucerne lakes, its banks exhibit the peculiar charm of rich and high cultivation.

Zürich, the capital city of this canton, stands on the lake described in the preceding article, about 1270 feet above the level of the sea, at the point where the beautifully translucent river Limmat gushes out and passes under a very broad wooden bridge, which is the chief market-place. The city contains 14,500 inhabitants, who are industrious, economical, and consequently thriving. They conduct considerable manufactories of silk, linen, and cotton; and this is the focal point for the sale of the goods prepared in the populous vicinity. A few years ago it might have been described as a gloomy ill-built place, and by no means a clean one; but of late the advance of wealth is abundantly shown in the great improvements which have been and still are carrying on. This is especially remarkable near the lake, and in the post-office and two hotels, one of which (the Bauer) is the largest and most complete establishment in Switzerland, if not in Europe. The university was only founded in 1823, and has never had many students. It was, in 1839, the pretext or the cause of a revolution in the canton. Dr Strauss, a man of learning, but the author of a work of infidel tendency, had been appointed professor of divinity. There had been discontents for some time in the parts of the canton without the city, against the municipality, who were the electors of a disproportionate number of the legislative body. This election to the professorship was made by that corporation, previously suspected of antichristian principles; and the country people flew to arms, besieged and took the city, displaced the municipality, ejected Strauss, and made alterations in the elections to favour the anti-capital party. Tranquillity was restored, after some lives had been lost; but how durable it may be, time must determine. The markets are well supplied with fruit and vegetables, and tolerably well with meat and poultry. Though the river and the lake furnish some fine fish, they are high in price when compared with other articles of food. The city was fortified, but is not kept in a very defensible state; some of its works having been formed into most pleasing walks, with views over the lake, and the snowy tops of the distant Alps in sight in the back-grounds. One of the defences of Zürich is the lake itself, on which an attempt was made by the French in 1799 to attack the city by water, on which occasion the inhabitants armed all the craft they could collect for the defence, and placed the flotilla under the command of a British naval officer of the name of Williams.

ZUTPHEN, a circle of the province of Guelderland in Holland, divided into fourteen cantons, and containing 84,000 inhabitants. The capital is the city of the same name, situated at the point where the river Berkell falls into the Yssel. It is strongly fortified, and the walls, being planted with trees, form a pleasing promenade. In the suburbs are many fine houses and gardens belonging to the merchants of the city. Zutphen contains six churches, several good schools, and 10,200 inhabitants, who have manufactories of cottons and linens, tanneries, breweries, distilleries, and paper-mills. Long. 5. 57. E. Lat. 52. 7. 30. N.

ZUYDER-ZEE, a great gulf or bay of the German Ocean, which extends from south to north in the United Provinces, between Friesland, Overyssel, Guelderland, and Holland. It is so called from its situation towards the south. It is said that the Zuyder-zee was formerly a lake, and that the land is swallowed up which united North Holland with Friesland.

ZWEIBRUCKEN, better known under the name of DEUX PONTS, a beautiful city, once the capital of a principality, but now belonging to the Rhenish province of the kingdom of Bavaria. It stands on the river Erblach, and is surrounded with walls. It is well and regularly built, in a fine situation, with hills and woods around it. The princely residence is in a ruinous condition, and a part of it is converted into a catholic church. Two of the churches are celebrated as fine specimens of architecture. The city contains 7250 inhabitants, employed in making cloths, leather, snuff, and tobacco. The learned society which existed here during the last century, and published some of the best Greek and Roman classics, is extinct.

ZWENIGORODKA, a circle of the Russian government of Kiew. It extends in north latitude from 48° 44′ to 49° 20′, and in east longitude from 30° 28′ to 32° 2′. It is watered chiefly by the Lincuska, the Zingley, and the Bojarka; has very little wood, but many valuable tracts of land, which, when cultivated, yield good corn. The capital is of the same name, on the river Zingley, and though called a city, has only 200 houses, with 1230 inhabitants. It is distant 1003 miles from St Petersburg. Long. 30. 44. E. Lat. 49. 12. N.

ZWICKAU, a city of the kingdom of Saxony, the capital of a bailiwick of the same name, in the province of Erzgebirge. It was formerly a strong fortification. It is now a well-built place, containing four churches, a college with a library of 16,000 volumes, a hospital, two military magazines, 890 houses, and 6000 inhabitants, who manufacture woollen and cotton goods, leather, and some hardware. Near to it are several mills for making paper.

ZWOLLE, a city, the capital of the circle of the same name, in the province of Overyssel, in Holland. It stands on a canal two miles from the Yssel, and is very strongly fortified. It is well and regularly built, and has eight churches, some hospitals, and a large grammar-school. Zwolle contains 15,640 inhabitants, among whom are many rich capitalists, who trade extensively in the products of the country, and conduct some large sugar-refineries. The city is surrounded with pleasant promenades.

ZYGHUR, a town of Hindustan, in the province of Bejapore and district of Concan, situated at the bottom of Boria Bay, which is two miles deep and six broad, but has only two and a half fathoms of water on the bar, though there is a good depth inside. The town is defended by a small citadel, and mostly enclosed with a stone wall. Long. 73. 23. E. Lat. 17. 16. N.

ZYMOSIMETER (formed from ζύμωσις, *fermentation*, and μέτρον, *measure*) is the name given to an instrument described by Swammerdam in his book *De Respiratione*, and intended to measure the degree of fermentation occasioned by the mixture of different matters, and the degree of heat which those matters acquire in fermenting. The same instrument has been employed to ascertain the heat or temperament of the blood of animals.

THE END.

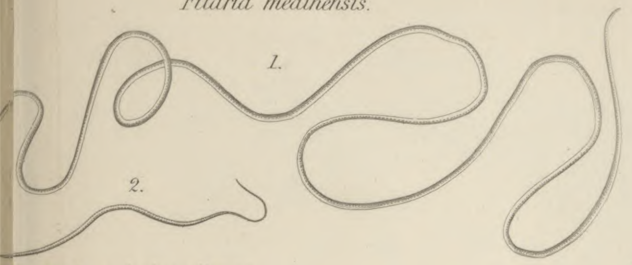
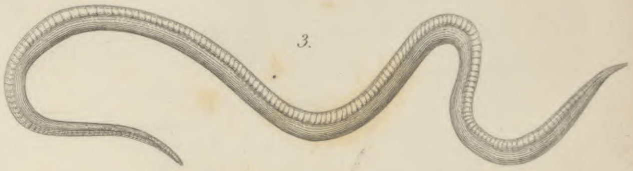
Engraved by S. Hall Bury Strt. Bloomsbury

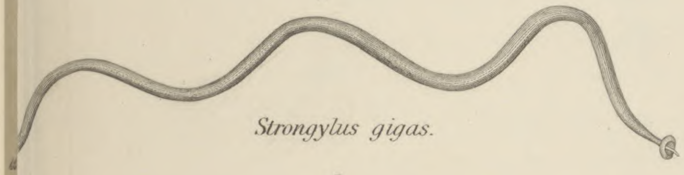


Filaria medinensis.

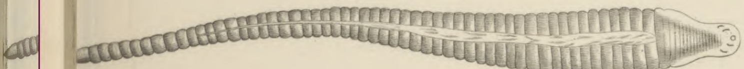
Trichocephalus dispar.



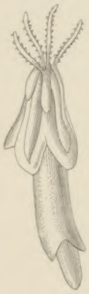
Ascaris lumbricoides.



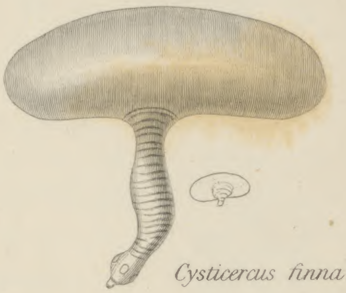
Strongylus gigas.



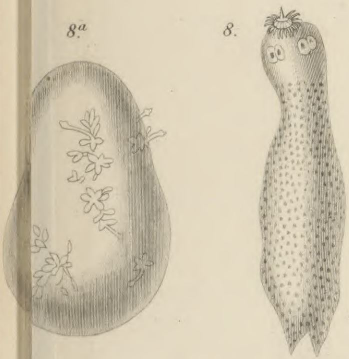
Linguatula tœnioides.



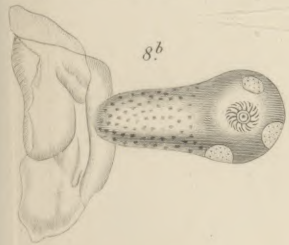
Tetrarhynchus lingualis.

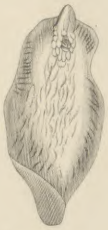


Cysticercus finna.

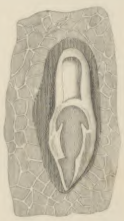


Cœnurus cerebralis.

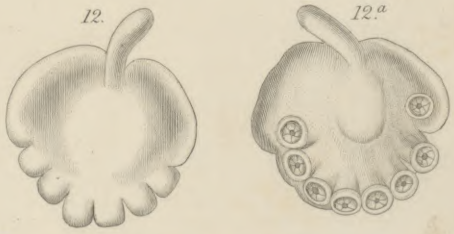




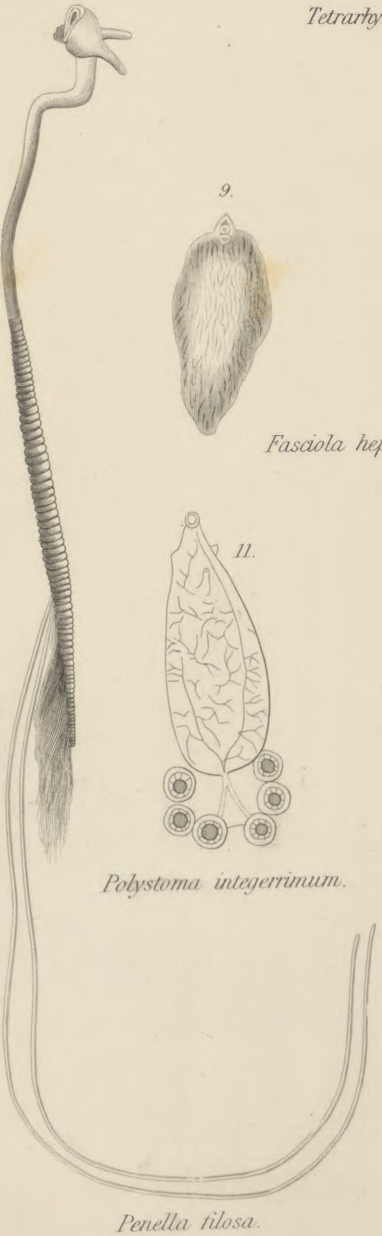
Fasciola hepatica.



Polystoma pinguicola.

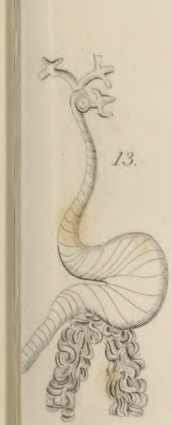


Cyclocotyles Bellones.

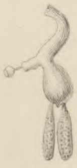


Polystoma integerrimum.

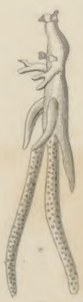
Penella filosa.



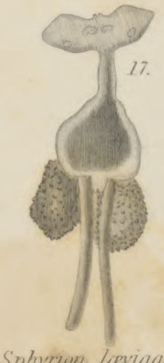
Lernœa branchialis.



Anchorella lagenula.

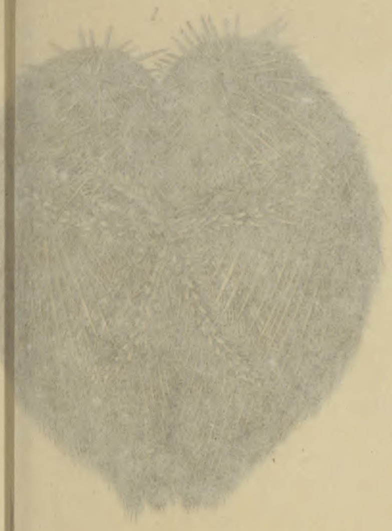


Chondrocanthus xyphiæ.

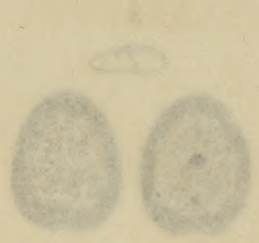


Sphyrion lævigatus.

Geo. Aikman. Sculpt.

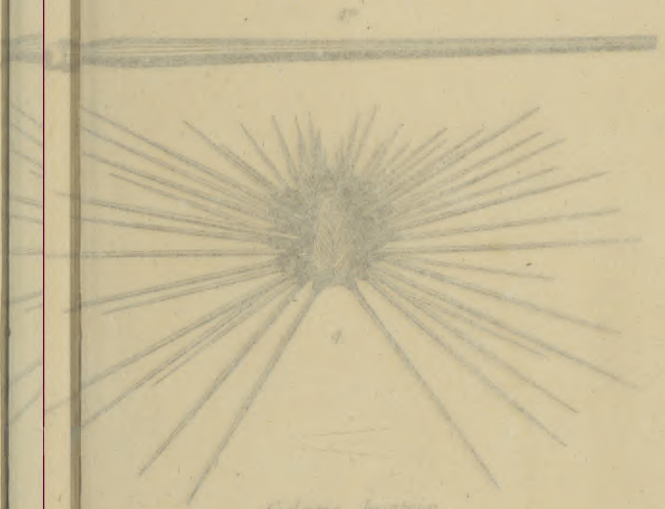


Spatangus purpureus.



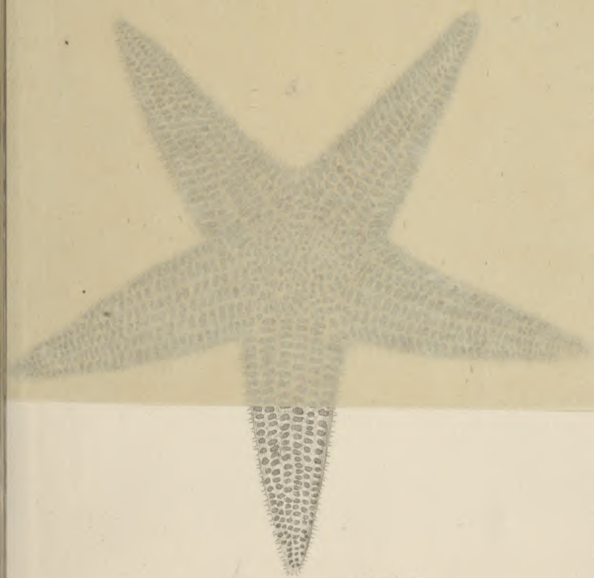
Echinocyamus minutus.

[illegible]

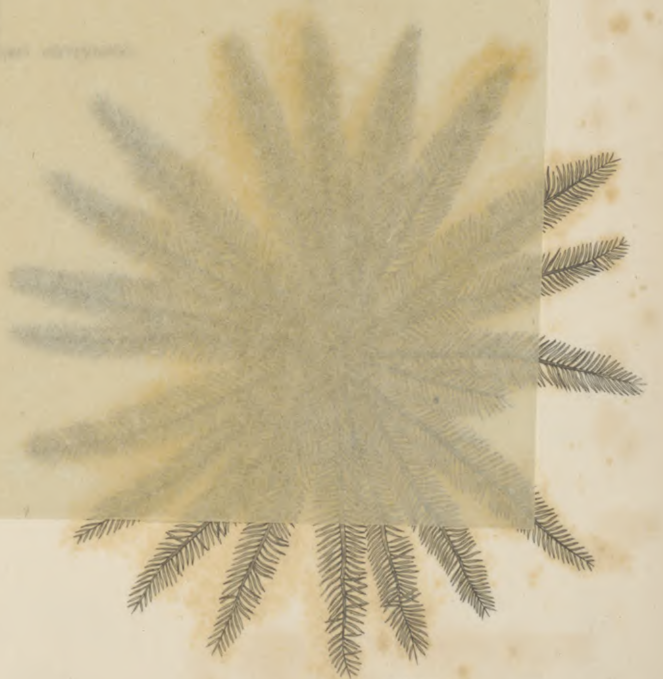


Cidaris hystrix.

[illegible]



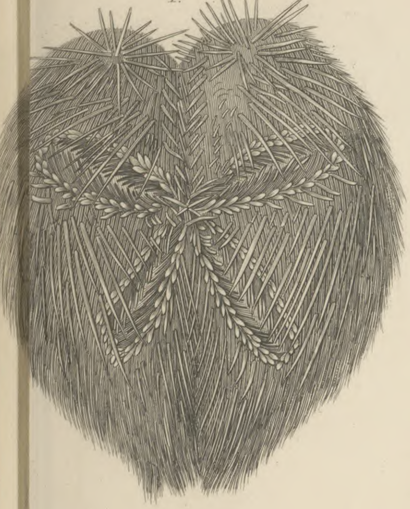
Asterias rubens, Blainv.



Comatula Adeonae.

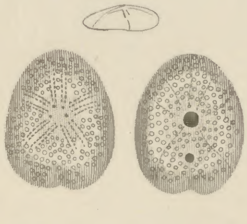
Geo. Aikman, Sculpt.

1.



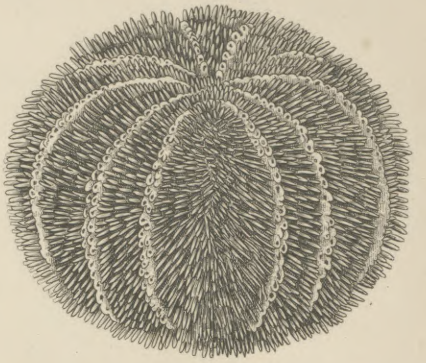
Spatangus purpureus.

2.



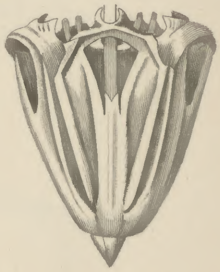
Echinocyanus minutus.

3.

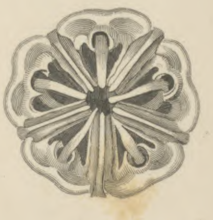


Echinus esculentus.

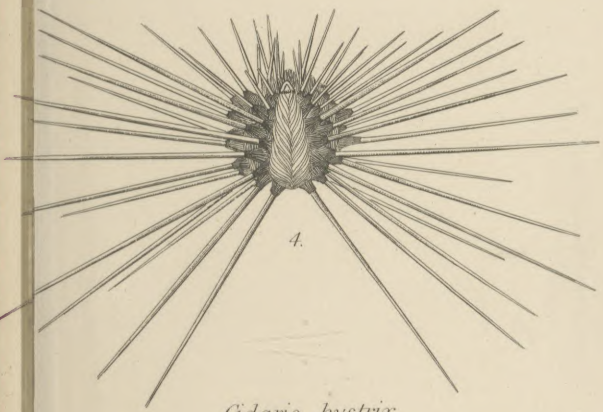
3.^{a}



3.^{b}

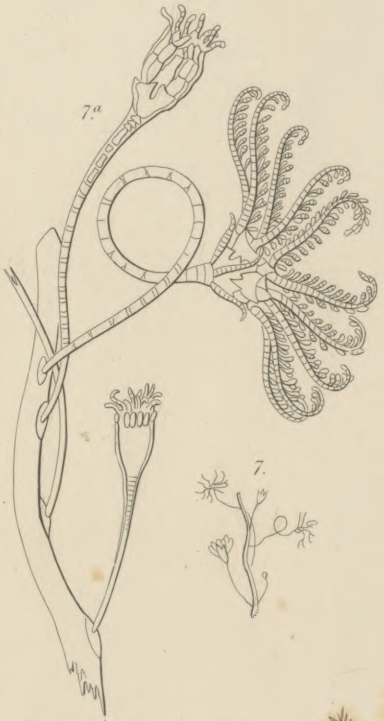


4.^{a}



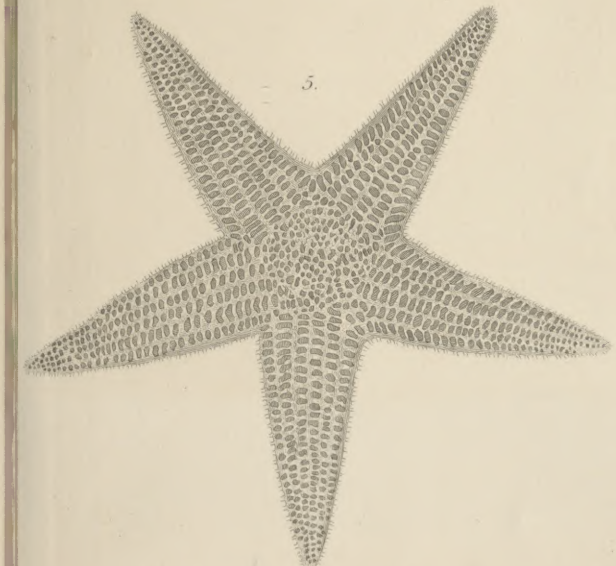
4.

Cidaris hystrix.



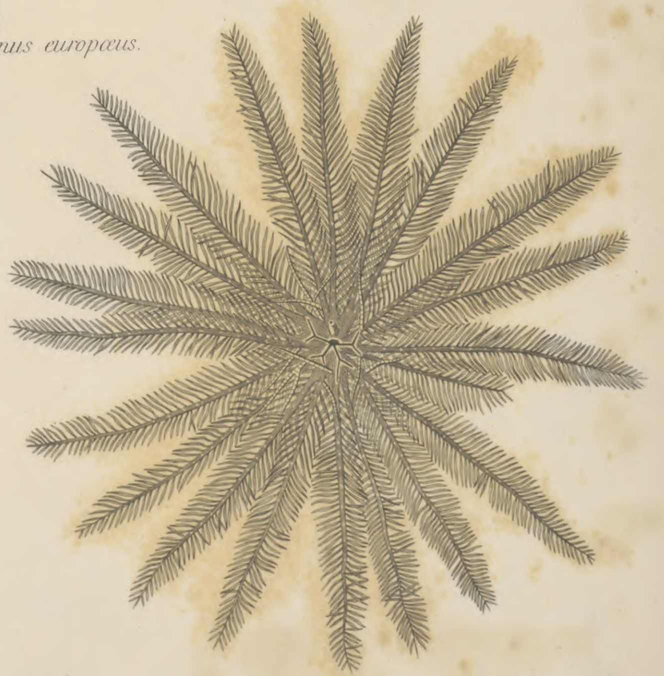
Pentacrinus europæus.

5.



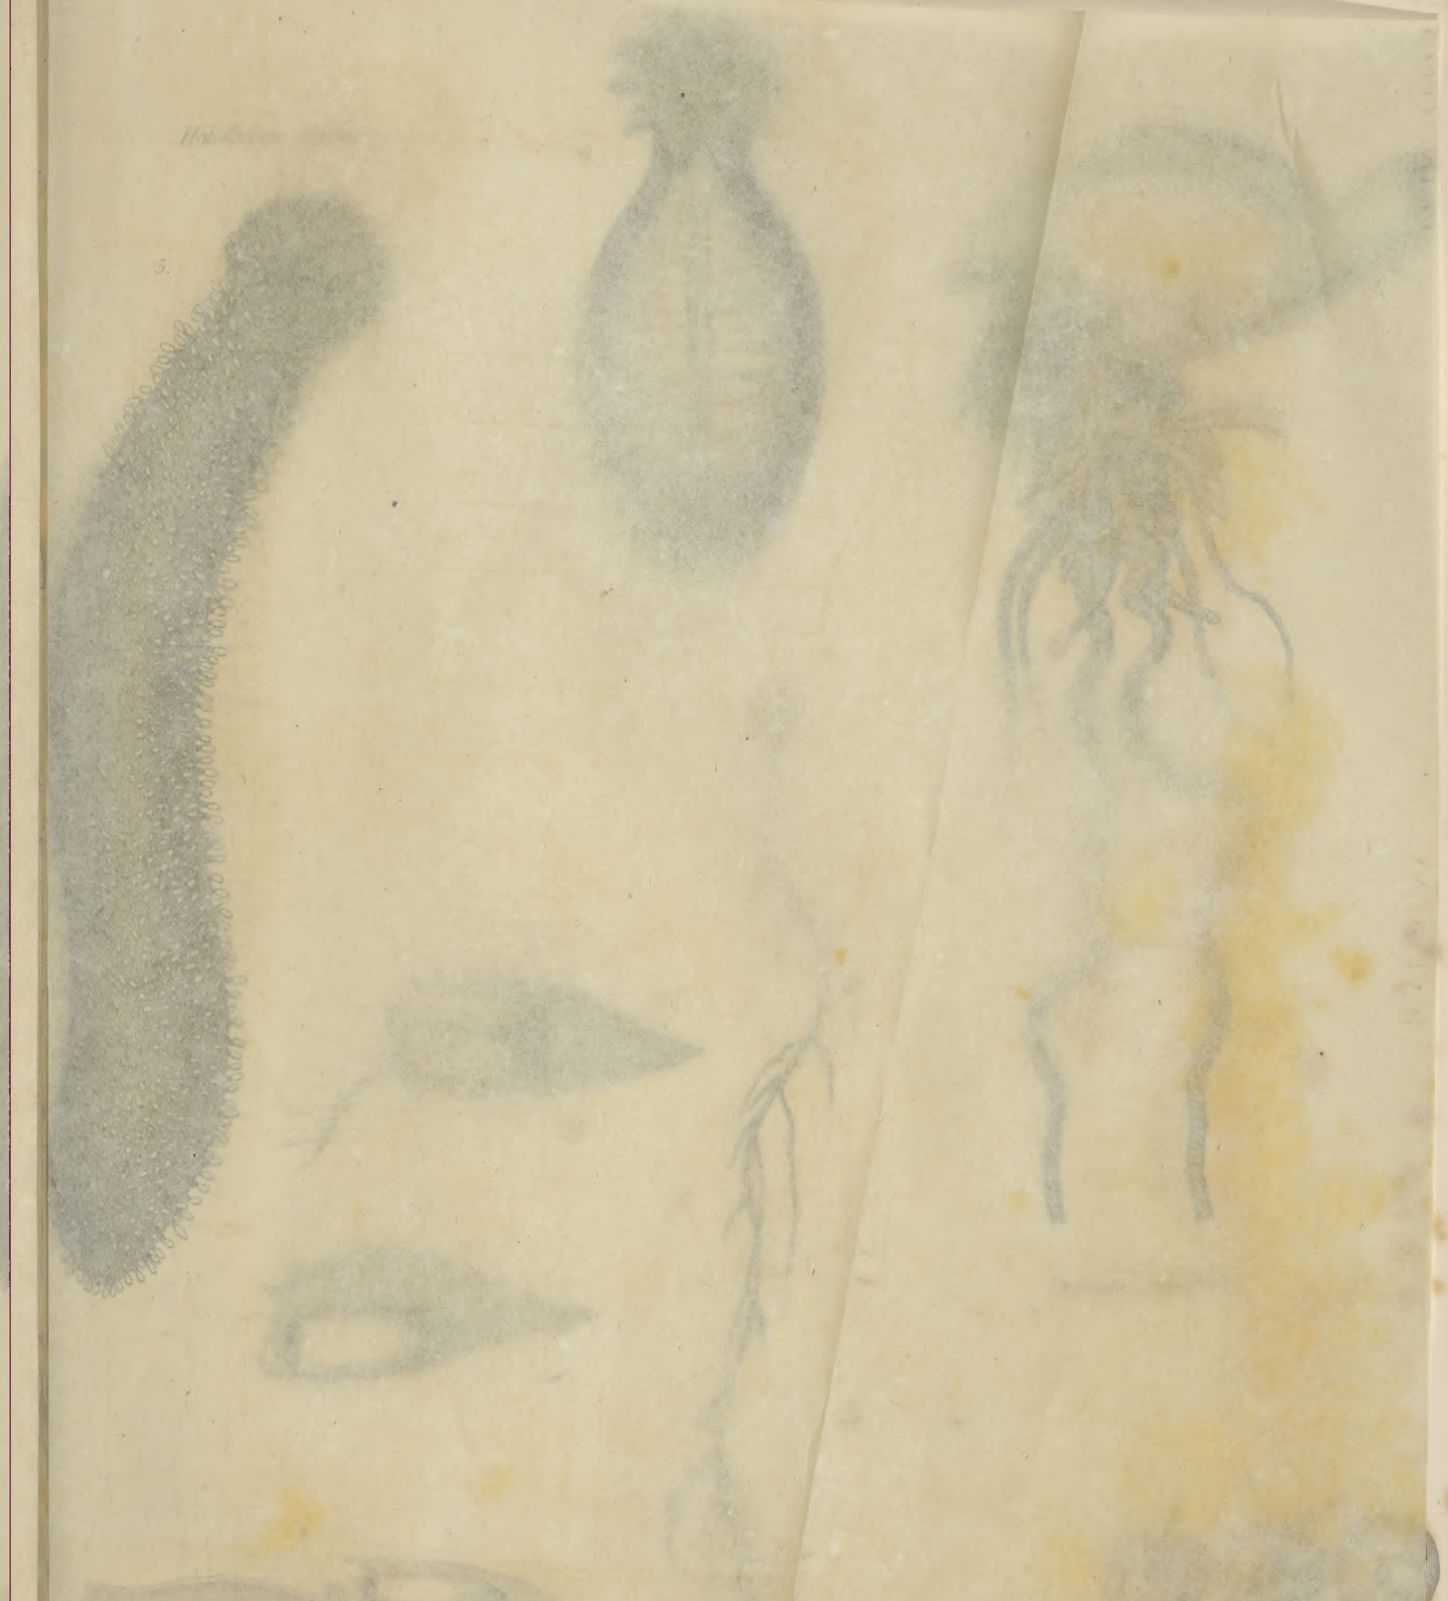
Asterias rubens, Blainv.

6.



Comatula Adeonae.

Geo. Aikman, Sculpt.



Diphye campanulifera.

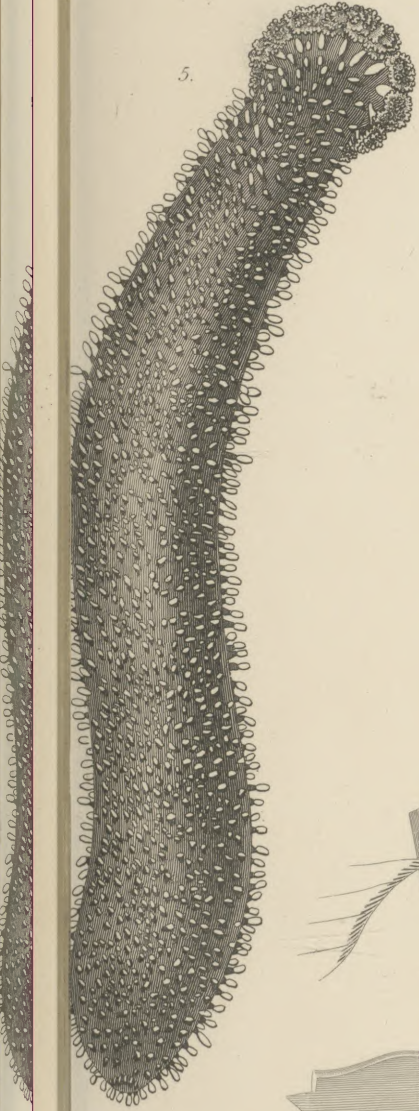
Rhizophysa filiformis.

Geo. Aikman, Sculpt.

ZOOPHYTES.

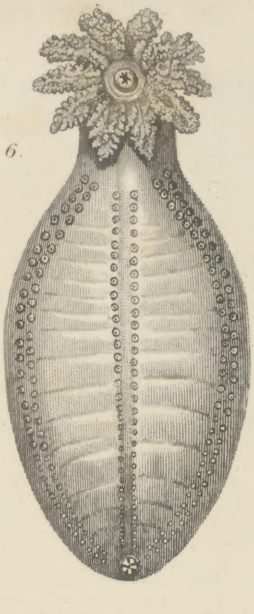
PLATE DIV.

5.



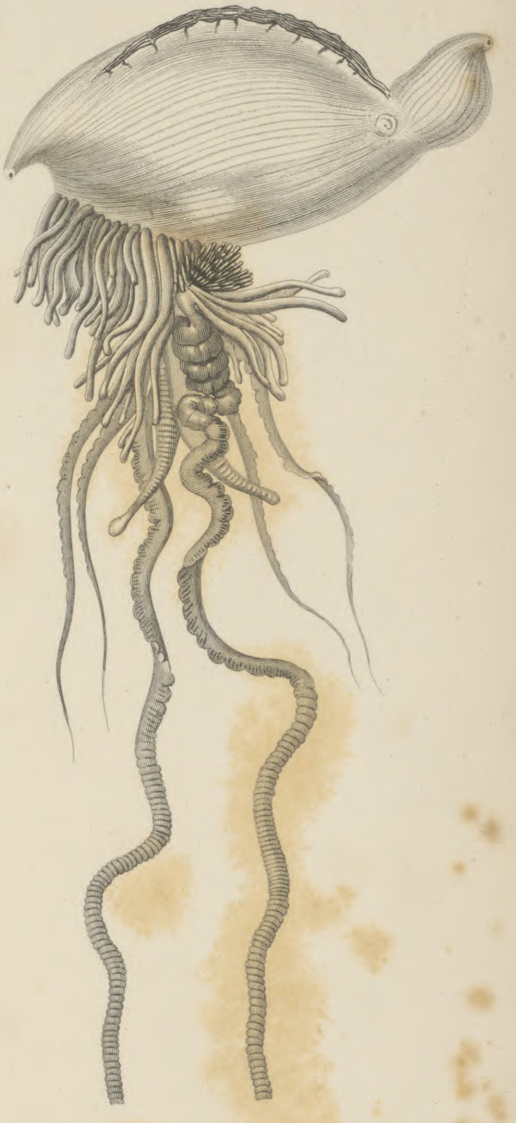
Holothuria tubulosa.

6.



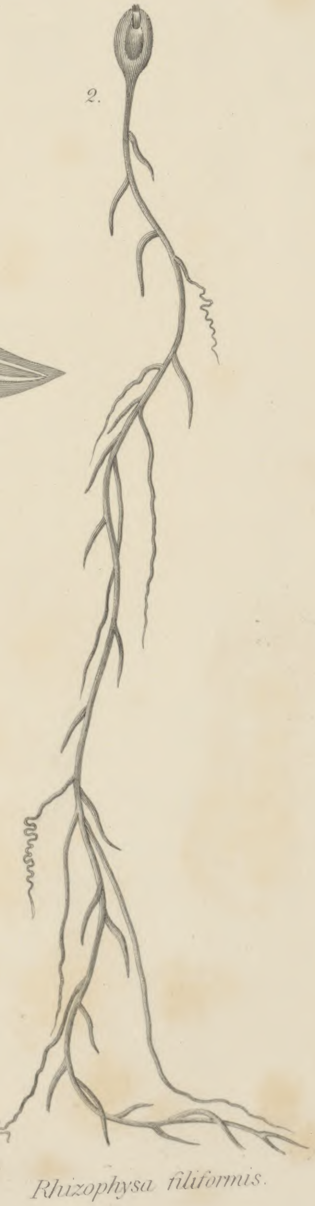
Holothuria papillosa.

1.



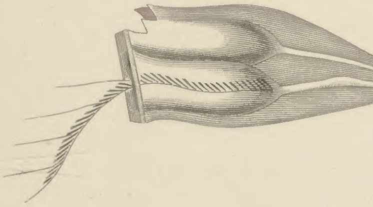
Physalus pelagica.

2.

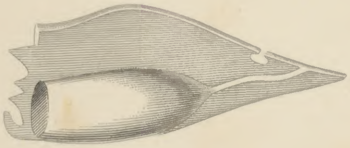


Rhizophysa filiformis.

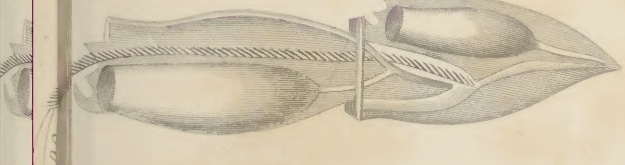
3.ª



3.ᵇ

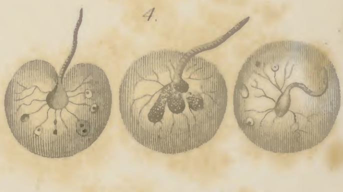


3.



Diphye campanulifera.

4.



Noctuluca miliaris.

Geo. Aikman, Sculp.ᵗ

1.

Pelagia panopyra.

2.

Rhizostoma Aldrovandi.

roe (Idya) elongatus.

4

Berenice eurisochroma.

[illegible] vermiculata.

6.

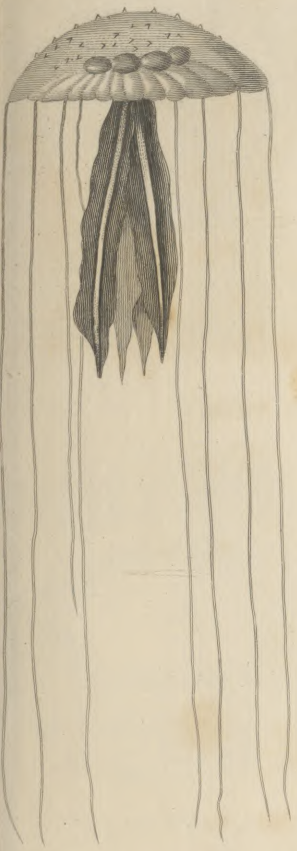
Cestum Veneris.

7.

Velella limbosa.

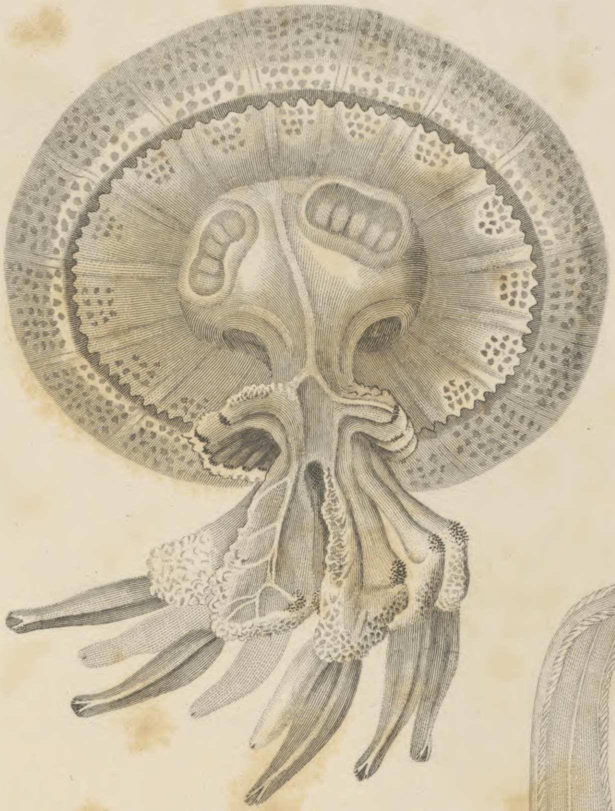
Geo. Aikman, Sculp.

1.

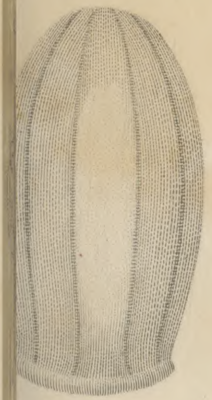


Pelagia panopyra.

2.

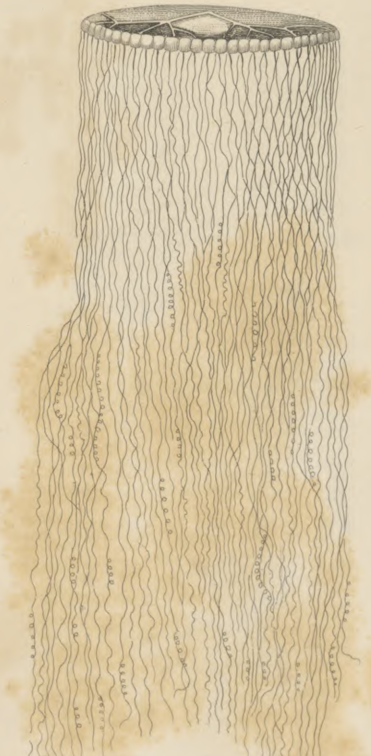


Rhyzostoma Aldrovandi.



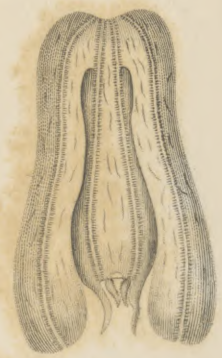
roe(Idya) elongatus.

4.



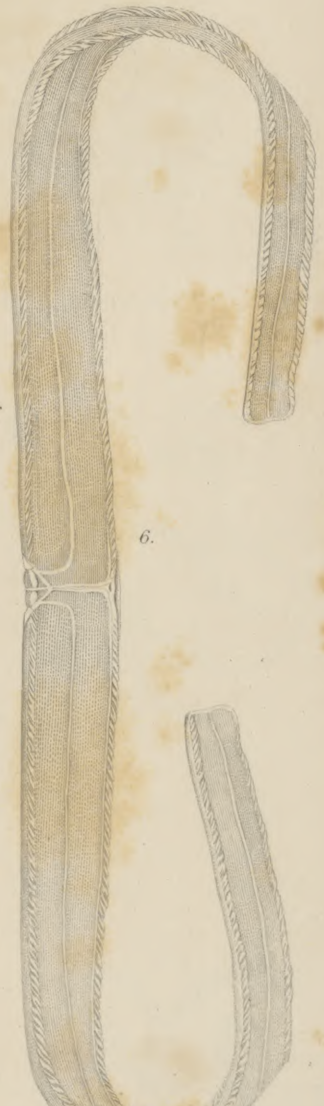
Berenice eurisochroma.

5.



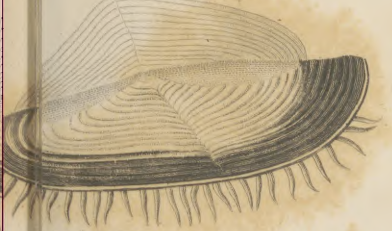
Alcinoe vermiculata.

6.



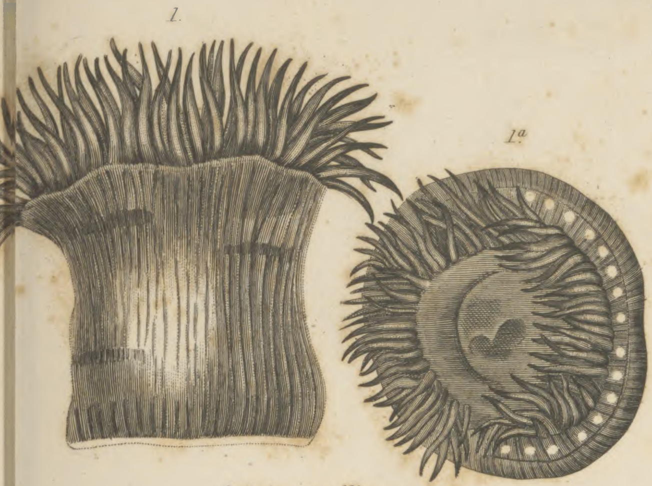
Cestum Veneris.

7.



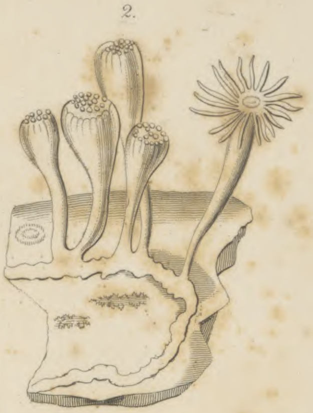
Velella limbosa.

Geo. Aikman, Sculp.t



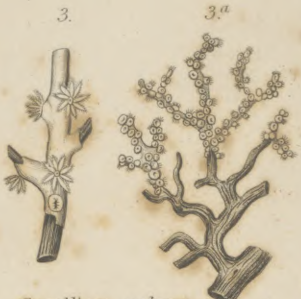
1. 1a

Actinia corallina.



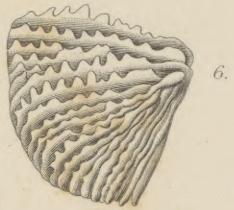
2.

Zoanthus sociatus.

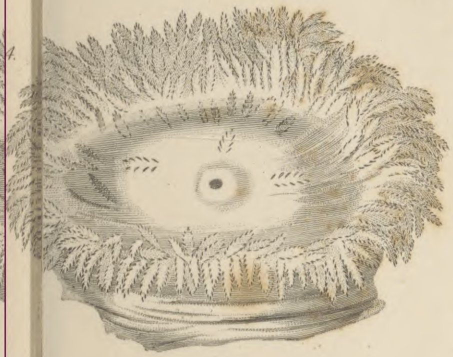


3. 3.a

Corallium rubrum.

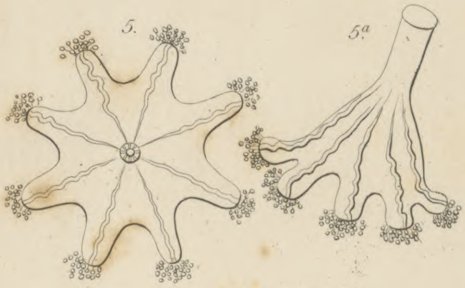


6.



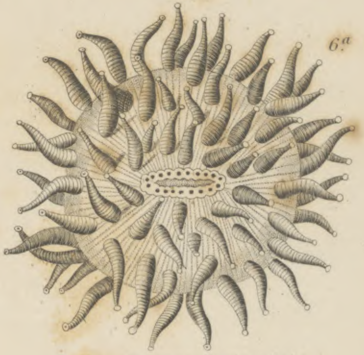
4.

Thalassiananthos aster.



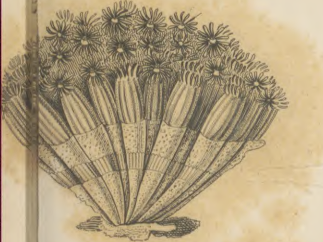
5. 5a

Lucernaria campanula.

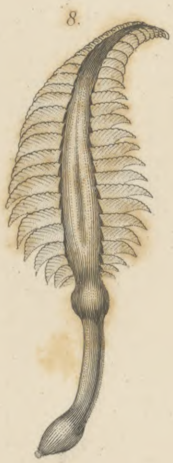


6a

Fungia crassitentaculata.

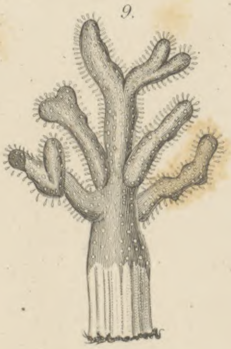


aryophyllia fasciculata.



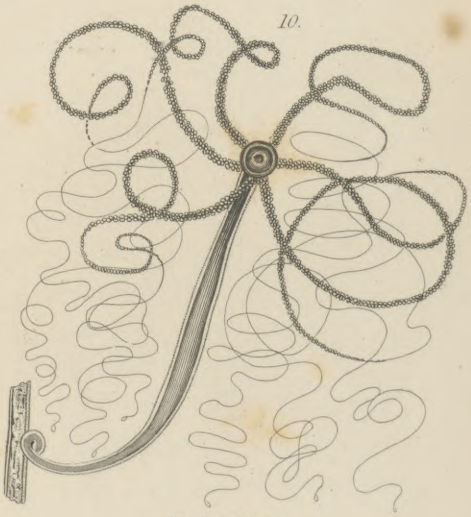
8.

Pennatula grisea.



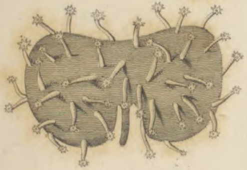
9.

Alcyonium aurantiacum.



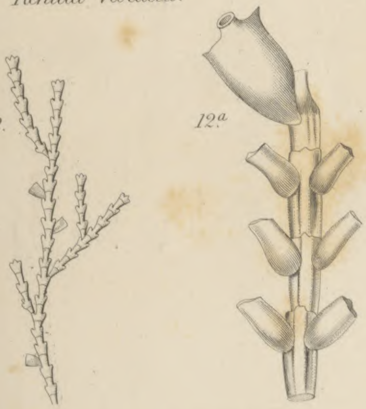
10.

Hydra fusca.



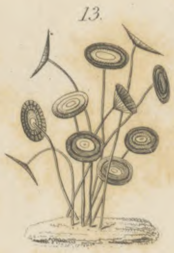
11.

Renilla violacea.



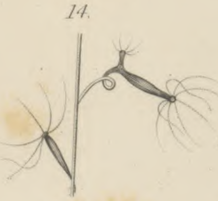
12. 12a

Sertularia tamarisca.



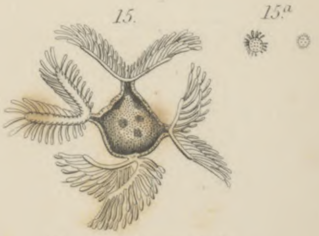
13.

Acetabulum mediterraneum.



14.

Hydra fusca.



15. 15a

Crystalella mucedo.

Geo. Aikman. Sculpt.
